**Introduction**  
New features ........................................ ...   2  
Hardware and software requirements .........   2  
About the manuals ...................................   2  
  Typographic conventions ..........................   3  
Software registration and technical support ....   4

**Chapter 1**  
Getting started with Turbo Assembler  
Installing Turbo Assembler ............................  5  
  The Turbo Assemblers ...................................  6  
Utility and example programs .........................  6  
Online Help ...........................................  7  
Writing your first Turbo Assembler program .......  7  
  Assembling your first program .......................  8  
  Linking your first program ...........................  9  
Recommended reading ..................................  9

**Chapter 2**  
Using directives and switches  
Starting Turbo Assembler .............................. 11  
Command-line options .................................. 13  
Indirect command files ................................ 26  
The configuration file .................................. 27

**Chapter 3**  
General programming concepts  
Turbo Assembler Ideal mode ......................... 29  
  Why use Ideal mode? .................................. 30  
  Entering and leaving Ideal mode ...................... 30  
  MASM and Ideal mode differences .................... 31  
  Expressions and operands ............................ 31  
    Operators ........................................... 32  
  Suppressed fixups ................................... 32  
  Operand for BOUND instruction ....................... 32  
  Segments and groups ................................ 33  
    Accessing data in a segment belonging to a group .... 33  
Commenting the program ................................ 35  
  Comments at the end of the line ....................... 35  
  The COMMENT directive ................................ 35  
Extending the line .................................... 36  
Using INCLUDE files ................................... 37  
Predefined symbols ................................... 37  
Assigning values to symbols ......................... 38  
General module structure ............................. 38  
  The VERSION directive ................................ 39  
  The NAME directive .................................. 40  
  The END directive ................................... 40  
Displaying a message during assembly ............... 40  
Displaying warning messages ......................... 41  
Multiple error-message reporting ..................... 42

**Chapter 4**  
Creating object-oriented programs  
Terminology .......................................... 43  
Why use objects in Turbo Assembler? ............... 44  
What is an object? ..................................... 44  
  A sample object ...................................... 45  
  Declaring objects .................................... 45  
    Declaring a base object ............................. 45  
    Declaring a derived object ......................... 47  
Declaring a method procedure ......................... 48  
The virtual method table ................................ 49  
  Initializing the virtual method table ............... 50  
Calling an object method ............................... 50  
  Calling a static method ............................... 50  
  Calling a virtual method ............................. 51  
  Calling ancestor virtual methods ..................... 53  
More on calling methods ................................ 54  
Creating an instance of an object ...................... 55  
Programming form for objects ......................... 55

**Chapter 5**  
Using expressions and symbol values  
Constants .............................................. 57  
    Numeric constants .................................. 57  
      Changing the default radix ....................... 58  
    String constants .................................. 58  
Symbols ................................................. 59  
    Symbol names ...................................... 59  
    Symbol types ...................................... 59  
    Simple address subtypes ............................. 60  
    Describing a complex address subtype ............... 61  
Expressions ............................................ 61  
    Expression precision ................................ 62  
    Constants in expressions ............................ 62  
    Symbols in expressions ............................... 62  
      Registers ......................................... 62  
      Standard symbol values ............................ 63  
Simple symbol values .................................. 63
## Chapter 10
### Declaring procedures 115
- Procedure definition syntax 115
- Declaring NEAR or FAR procedures 116
- Declaring a procedure language 118
- Specifying a language modifier 119
- Defining arguments and local variables 120
- ARC and LOCAL syntax 121
- The scope of ARC and LOCAL variable names 122
- Preserving registers 123
- Defining procedures using procedure types 123
- Nested procedures and scope rules 124
- Declaring method procedures for objects 125
- Using procedure prototypes 126

## Chapter 11
### Controlling the scope of symbols 129
- Redefinable symbols 129
- Block scoping 130
  - The LOCALS and NOLOCALS directives 130
  - MASM block scoping 131
- MASM-style local labels 131

## Chapter 12
### Allocating data 133
- Simple data directives 134
- Creating an instance of a structure or union 137
  - Initializing union or structure instances 137
- Creating an instance of a record 140
  - Initializing record instances 140
- Creating an instance of an enumerated data type 141
  - Initializing enumerated data type instances 141
- Creating an instance of a table 141
  - Initializing table instances 142
- Creating and initializing a named-type instance 142
- Creating an instance of an object 143
- Creating an instance of an object’s virtual method table 143

## Chapter 13
### Advanced coding instructions 145
- Intelligent code generation: SMART and NOSMART 145
- Extended jumps 146
- Additional 80386 LOOP instructions 147
- Additional 80386 ENTER and LEAVE instructions 147
- Additional return instructions 147
- Additional IRET instructions 148
- Extended PUSH and POP instructions 148
  - Multiple PUSH and POPs 148
  - Pointer PUSH and POPs 148
  - PUSHing constants on the 8086 processor 149
- Additional PUSHA, POPA, PUSHF and POPF instructions 149
- The PUSHSTATE and POPSTATE instructions 149
- Extended shifts 151
- Forced segment overrides: SEGxx instructions 151
- Additional smart flag instructions 151
- Additional field value manipulation instructions 152
  - The SETFIELD instruction 152
  - The GETFIELD instruction 153
- Additional fast immediate multiply instruction 154
- Extensions to necessary instructions for the 80386 processor 154
- Calling procedures with stack frames 155
  - Calling procedures that contain RETURNS 156
  - Calling procedures that have been prototyped 156
  - Calling method procedures for objects: CALL.METHOD 157
  - Tail recursion for object methods: JMP.METHOD 158
- Additional instruction for object-oriented programming 158

## Chapter 14
### Using macros 159
- Text macros 159
  - Defining text macros with the EQU directive 159
String macro manipulation directives ............................ 160
The CATSTR directive ........................................ 160
The SUBSTR directive ........................................ 160
The INSTR directive .......................................... 161
The SIZESTR directive ...................................... 161
Text macro manipulation examples ............................. 161
Multiline macros ................................................ 161
The multiline macro body ...................................... 162
Using & in macros ............................................. 162
Including comments in macro bodies ......................... 163
Local dummy arguments .................................... 163
The EXITM directive .......................................... 164
Tags and the GOTO directive .................................. 164
General multiline macros ..................................... 165
Invoking a general multiline macro ......................... 166
The < > literal string brackets ............................. 166
The ! character ................................................ 167
The % expression evaluation character .................... 167
Redefining a general multiline macro ....................... 168
Deleting a general multiline macro: ......................... 168
Defining nested and recursive macros ...................... 168
The count repeat macro ...................................... 169
The WHILE directive .......................................... 170
String repeat macros .......................................... 170
The % immediate macro directive .......................... 171
Including multiline macro expansions in the list file 172
Saving the current operating state ........................... 172
Chapter 15
Using conditional directives ................................. 175
General conditional directives syntax ....................... 175
IFxxx conditional assembly directives .................... 175
ELSEIFxxx conditional assembly directives ............. 177
ERRxxx error-generation directives ....................... 177
Specific directive descriptions ........................... 178
Unconditional error-generation directives ............... 178
Expression-conditional directives ......................... 178
Symbol-definition conditional directives ................. 179
Text-string conditional directives ......................... 180
Assembler-pass conditionals .................................. 182
Including conditionals in the list file ..................... 182
Chapter 16
Interfacing with the linker ..................................... 183
Publishing symbols externally .............................. 183
Conventions for a particular language .......................... 183
Declaring public symbols ................................... 184
Declaring library symbols ................................... 184
Defining external symbols .................................... 185
Defining global symbols ..................................... 185
Publishing a procedure prototype .......................... 185
Defining communal variables ............................... 186
Including a library ........................................... 187
The ALIAS directive .......................................... 187
Chapter 17
Generating a listing ............................................. 189
Listing format .................................................. 189
General list directives ....................................... 190
Include file list directives .................................. 191
Conditional list directives ................................... 191
Macro list directives ........................................ 192
Cross-reference list directives ............................. 193
Changing list format parameters ............................ 194
Chapter 18
Interfacing Turbo Assembler with Borland C++ ............. 197
Calling Turbo Assembler functions from Borland C++ 197
The framework .................................................. 198
Linking assembly language modules with C++ ............... 198
Using Extern "c" to simplify linkage .......................... 200
Memory models and segments ................................ 200
Simplified segment directives and Borland C++ .................. 200
Old-style segment directives and Borland C++ ............... 202
Segment defaults: When is it necessary to load segments? 203
Publics and externals ........................................... 205
Underscores and the C language .............................. 205
The significance of uppercase and lowercase .............. 206
Label types ....................................................... 207
Far externals ..................................................... 208
Linker command line ........................................... 209
Parameter passing .............................................. 209
Preserving registers .......................................... 213
Returning values ............................................... 214
Calling an assembler function from C++ ..................... 215
Writing C++ member functions in assembly language ....... 218
Pascal calling conventions .................................. 220
Calling Borland C++ from Turbo Assembler .................. 221
Link in the C++ startup code .................................. 221
The segment setup ............................................. 221
Tables

1.1 Turbo Assemblers .................................. 6
4.1 Object-oriented programming terminology ....... 43
4.2 Symbols defined for objects ................... 44
5.1 Radices ........................................... 57
5.2 Characters determining radices .................. 58
5.3 Numeric constants ................................ 58
5.4 Symbol types .................................... 59
5.5 Address subtypes .................................. 60
5.6 Complex address subtypes ...................... 61
5.7 Distance syntax .................................. 61
5.8 Simple expressions .............................. 62
5.9 Standard symbols .................................. 63
5.10 Values of symbols used by themselves ....... 63
5.11 LENGTH operator return values ............. 64
5.12 SIZE values ..................................... 65
5.13 WIDTH values ................................... 65
5.14 MASK return values ............................. 66
5.15 Simple arithmetic operators .................... 66
5.16 Logical arithmetic operators ................... 66
5.17 Bit shift operators .............................. 67
5.18 Comparison operators ............................ 67
5.19 Type override operators ....................... 67
5.20 TYPE values .................................... 68
5.21 Bit fields from SYMTYPE and .TYPE ......... 71
6.1 Processor directives .............................. 76
6.2 8087 coprocessor directives .................... 78
7.1 Standard memory models ......................... 83
7.2 Model modifiers ................................... 84
7.3 Model modifiers ................................... 85
7.4 Simplified segment directives ................... 86
7.5 Symbols from simplified segment directives .. 87
7.6 Segment combination attribute .................. 88
7.7 Segment alignment attribute .................... 89
7.8 Segment size attribute values .................. 90
7.9 Segment access attribute ....................... 90
7.10 Stack size modification directives .......... 94
8.1 STRUC, UNION, and ENDS directives ......... 100
8.2 Block members ................................... 101
8.3 Available modifiers ............................. 106
8.4 Symbols used or defined by STRUC .......... 107
12.1 Data size directives ........................... 134
13.1 Intelligent code generation directives ....... 145
13.2 Return instructions ............................. 147
13.3 Segment override instructions ................ 151
13.4 Smart flag instructions ....................... 152
13.5 Instructions for setting and retrieving values 152
13.6 Instructions affected by SMALL and LARGE .......... 154
14.1 Dummy argument types ........................... 166
14.2 Uses for the ! character ....................... 167
15.1 Conditional assembly directives using expressions .... 178
15.2 Error-generation directives using expressions .... 179
15.3 Evaluation of defined and undefined symbol .......... 179
15.4 Symbol-expression directives using symbol_expr ........ 179
15.5 Error-generation directives ................... 180
15.6 Conditional assembly directives using text_strings .... 180
15.7 Error-generation directives using text_strings .... 181
18.1 Register settings when Borland C++ enters assembler .... 203
A.1 Default segments and types for TINY memory model .......... 227
A.2 Default segments and types for SMALL memory model .... 227
A.3 Default segments and types for MEDIUM memory model .... 228
A.4 Default segments and types for COMPACT memory model .... 228
A.6 Default segments and types for Borland C++ HUGE memory model ........ 228
A.6 Default segments and types for Borland C++ HUGE (TCHUGE) memory model .... 229
B.1 Turbo Assembler v1.0 keywords ................ 243
B.2 Turbo Assembler v2.0 new keywords ........... 245
B.3 Turbo Assembler v2.5 new keywords ........... 246
B.4 Turbo Assembler v3.0 new keywords ........... 246
B.5 Turbo Assembler v3.1 new keywords ........... 246
B.6 Turbo Assembler v3.2 new keywords ........... 246
B.7 Turbo Assembler v4.0 new keywords ........... 246
B.8 Turbo Assembler v5.0 new keywords ........... 247
B.9 Options supported by OPTION ................... 247
C.1 Turbo Assembler types and their equivalent directives .... 249
C.2 Signed integer data types ...................... 250
C.3 Floating-point data types ...................... 250
C.4 New Turbo Assembler logical operators .......... 253
C.5 Return value of SIZE in MASM mode ........... 257
Welcome to Borland’s Turbo Assembler,® a multi-pass assembler with forward-reference resolution, assembly speeds of up to 48,000 lines per minute (on an IBM PS/2 model 60), Microsoft Macro Assembler (MASM) compatibility, and an optional Ideal mode extended syntax. Whether you’re a novice or an experienced programmer, you’ll appreciate these features and others we’ve provided to make programming in assembly language easier. Here are the highlights—we’ll describe them in detail later:

- Object-oriented programming capabilities
- 32-bit model and stack frame support
- Full 386, i486, and Pentium support
- Simplified segmentation directives
- Table support
- Enumerations
- Smart flag instructions
- Fast immediate multiply operation
- Multiline definition support
- VERSION specification directive
- Nested directives
- Quirks mode to emulate MASM
- Full source debugging output
- Cross-reference utility (TCREF)
- Configuration and command files
- File converter utility (converts C .h files to TASM .ash files)
- Procedure prototyping and argument checking capabilities
- Alias support
- Windows 95 flat thunking support

Turbo Assembler is a powerful command-line assembler that takes your source (.ASM) files and produces object (.OBJ) modules. You then use TLINK.EXE, Borland’s high-speed linker program, to link your object modules and create executable (.EXE) files.
New features

Turbo Assembler version 5.0 incorporates the following new feature enhancements:

- Enhanced MASM compatibility, as described in "MASM 6.1 compatibility" on page 249.
- Windows 95 flat thunking support with the -utthk command-line option. For more information on thunking, refer to the sample program and documentation contained in the subdirectory \EXAMPLES\THUNK95 off your main TASM directory.

Hardware and software requirements

Turbo Assembler generates instructions for the 8086, 80186, 80286, 80386, i486, Pentium, and Pentium Pro, and compatible processors. Essentially Turbo Assembler runs on all Intel-processor based computers, including all true compatibles. Turbo Assembler also generates floating-point instructions for the 8087, 80287, and 80387 numeric coprocessors. (For more information about the instruction sets of the 80x86/80x87 families, consult the Intel data books.)

About the manuals

Turbo Assembler comes with the Turbo Assembler User's Guide (this book) and the Turbo Assembler Quick Reference Guide. The User's Guide provides basic instructions for using Turbo Assembler, explores how to interface Turbo Assembler with other languages, and describes in detail the operators, predefined symbols, and directives Turbo Assembler uses. The Quick Reference Guide is a handy guide to directives and processor and coprocessor instructions.

Here's a more detailed look at what the User's Guide contains.

Chapter 1, "Getting started with Turbo Assembler," tells you how to install Turbo Assembler on your system.

Chapter 2, "Using directives and switches," describes how you can control the way the assembler runs when you use directives and switches.

Chapter 3, "General programming concepts," discusses the differences between Ideal and MASM modes, how to use predefined symbols, using comment characters, and so forth.

Chapter 4, "Creating object-oriented programs," describes how you can use object-oriented programming techniques in assembly language.

Chapter 5, "Using expressions and symbol values," talks about evaluating and defining expressions and operators.

Chapter 6, "Choosing processor directives and symbols," tells you how to generate code for particular processors.
Chapter 7, "Using program models and segmentation," talks about program models, creating symbols, simplified segments, and ordering of segments.

Chapter 8, "Defining data types," explains how to define structures, unions, tables, bit-field records, and objects.

Chapter 9, "Setting and using the location counter," describes how and why you'd want to use the location counter, as well as how to define labels.

Chapter 10, "Declaring procedures," examines how to use various types of procedures, and how to define and use arguments and local variables.

Chapter 11, "Controlling the scope of symbols," discusses how you can limit or expand the area in which a symbol has a particular value.

Chapter 12, "Allocating data," describes simple data directives, and how to create instances of structures, unions, records, enumerated data types, tables, and objects.

Chapter 13, "Advanced coding instructions," covers Turbo Assembler's extended instructions, including prototyping and calling language procedures.

Chapter 14, "Using macros," tells you how to use macros in your code.

Chapter 15, "Using conditional directives," talks about the directives that let you execute your code conditionally.

Chapter 16, "Interfacing with the linker," describes how you can include libraries and publish symbols as you link your code.

Chapter 17, "Generating a listing," talks about Turbo Assembler listing files and how to use them.

Chapter 18, "Interfacing Turbo Assembler with Borland C++," explains how to use Borland's line of C++ compilers with assembly language.

Appendix A, "Program blueprints," contains example program structures for Windows and DOS programs.

Appendix B, "Turbo Assembler syntax summary," illustrates Turbo Assembler expressions (both MASM and Ideal modes) in modified Backus-Naur form (BNF).

Appendix C, "MASM 6.1 compatibility," covers the differences between MASM and Turbo Assembler MASM mode.

Appendix D, "Error messages," describes all the error messages that can be generated when using Turbo Assembler: information messages, fatal error messages, warning messages, and error messages.

Typographic conventions

When we talk about IBM PCs or compatibles, we’re referring to any computer that uses the 8088, 8086, 80186, 80286, 80386, i486, Pentium, and Pentium Pro processors (all of these chips are commonly referred to as 80x86).
The following typefaces are used in this book:

*Italics* In text, italics represent labels, placeholders, variables, and arrays. In syntax expressions, placeholders are set in italics to indicate they are user-defined.

**Boldface** Boldface is used in text for directives, instructions, symbols, and operators, as well as for command-line options.

**CAPITALS** In text, capital letters are used to represent instructions, directives, registers, and operators.

**Monospace** Monospace type is used to display any sample code or text that appears on your screen, and any text that you must actually type to assemble, link, and run a program.

**Keycaps** In text, keycaps indicate a key on your keyboard. It is often used when describing a key you must press to perform a particular function; for example, “Press Enter after typing your program name at the prompt.”

---

**Software registration and technical support**

The Borland® Assist program offers a range of technical support plans to fit the different needs of individuals, consultants, large corporations, and developers. To receive help with this product, send in the registration card and select the Borland Assist plan that best suits your needs. North American customers can register by phone 24 hours a day by calling 1-800-845-0147.

For additional details on these and other Borland services, see the *Borland Assist and Services Guide* included with this product.
Getting started with Turbo Assembler

You might have heard that programming in assembly language is a black art suited only to hackers and wizards. However, assembly language is nothing more than the human form of the language of the computer. And, as you’d expect, the computer’s language is highly logical. As you might also expect, assembly language is very powerful—in fact, assembly language is the only way to tap the full power of the Intel 80x86 family, the processors at the heart of the IBM PC family and compatibles.

You can write whole programs using nothing but assembly language or you can mix assembly language with programs written in high-level languages such as Borland® C++ and Borland® Pascal. Either way, assembly language lets you write small and blindingly fast programs. In addition to the advantage of speed, assembly language gives you the ability to control every aspect of your computer’s operation, all the way down to the last tick of the computer’s system clock.

Installing Turbo Assembler

The Turbo Assembler package consists of a set of executable programs, utilities, and example programs. In addition, the package includes a Quick Reference Guide and this User’s Guide.

For instructions on installing Turbo Assembler, refer to the TSM_INST.TXT file on your installation disk:

1 Insert the TASM Install disk in drive A of your computer.

2 Use your text editor to open TSM_INST.TXT, or issue the following command at the command line:

    TYPE A:TSM_INST.TXT | MORE
The Turbo Assemblers

The Turbo Assembler package comes complete with 3 different assemblers, as outlined in Table 1.1:

Table 1.1 Turbo Assemblers

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TASM.EXE</td>
<td>Real-mode assembler. Assembles 16- and 32-bit .OBJs using the 640K memory space addressable by DOS. Produces only 16-bit debug information.</td>
</tr>
<tr>
<td>TASMX.EXE</td>
<td>Protected-mode assembler. Assembles 16- and 32-bit .OBJs using memory above 640K. Produces only 16-bit debug information.</td>
</tr>
</tbody>
</table>

All three assemblers are capable of producing both 16- and 32-bit object files, depending on the directives contained in your assembler source files. If you produce a 16-bit object file, then you must use the 16-bit linker (TLINK.EXE) to link your application. If you produce a 32-bit object file, then you must use the 32-bit linker (TLINK32.EXE) to link your application.

TASM.EXE is a real-mode assembler, meaning that it is capable of using only the lower 640K of memory addressable by DOS. If you’re assembling larger applications, use either TASMX.EXE or TASM32.EXE. Both of these assemblers use the DPMI server to take advantage of extended memory.

The biggest difference between the three assemblers is the type of debug information they produce when you assemble your source files with the /zi command-line option. Both TASM.EXE and TASMX.EXE produce only 16-bit debug information. TASM32.EXE produces only 32-bit debug information. If you plan to use Turbo Debugger to debug your assembler application, then you must assemble 16-bit files with either TASM.EXE or TASMX.EXE. To produce 32-bit debug information, then you must assemble your files with TASM32.EXE.

Utility and example programs

The Turbo Assembler package includes several utility programs to help you build assembly programs. The utilities include the Turbo Linkers, the MAKE utility, the GREP file search utility, and the resource compilers and linkers. These utility programs are described in the online text files located in the \DOC subdirectory located off your main TASM directory.

To get you started writing assembler programs, the Turbo Assembler package includes various example programs that demonstrate different assembler programming techniques. The example programs, located in the \EXAMPLES directory under the main TASM directory, even include complete 16- and 32-bit Windows assembly programs.
Online Help

You can get online Help for Turbo Assembler using the Windows Help facility. To access the online Help, do one of the following:

- From Windows, click the TASM Reference icon in the TASM program group
- From Windows, run the TASM.HLP file located in the \TASM\BIN subdirectory

You can run TASM.HLP from a DOS box in Windows. On the DOS command line, enter the following command from the \TASM\BIN directory:

winhelp tasm.hlp

Writing your first Turbo Assembler program

If you have not yet written an assembly program, the DOS-based “Greetings, World!” program is a good place to start. To begin writing this program, open your favorite program editor and enter the following lines of code to create the HELLO.ASM program:

```asm
.MODEL SMALL
.STACK 100h
.DATA

TimePrompt DB 'Is it after 12 noon (Y/N)?$'
GoodMorningMessage DB 13,10,'Good morning, world!',13,10,'$'
GoodAfternoonMessage DB 13,10,'Good afternoon, world!',13,10,'$'
DefaultMessage DB 13,10,'Good day, world!',10,13,'$'

.CODE
start:
mov ax,@data
mov ds,ax
mov dx,OFFSET TimePrompt
mov ah,9
int 21h
mov ah,1
int 21h
or al,20h
jmp DisplayGreeting

cmp al, 'y'
jbe IsAfternoon

cmp al, 'n'
jbe IsMorning

mov dx,OFFSET DefaultMessage
jmp DisplayGreeting

IsAfternoon:
mov dx,OFFSET GoodAfternoonMessage
jmp DisplayGreeting
```

Chapter 1, Getting started with Turbo Assembler 7
IsMorning:
    mov    dx,OFFSET GoodMorningMessage ;before noon greeting

DisplayGreeting:
    mov    ah,9
    int    21h ;DOS: print string
    mov    ah,4ch
    int    21h ;DOS: terminate program
    mov    al,0 ;return code will be 0
    int    21h ;terminate the program

END start

After you’ve entered the preceding program, save it to disk as HELLO.ASM. (For convenience, HELLO.ASM is supplied in the \EXAMPLES\USRGUIDE directory located under your main TASM directory.)

If you’re familiar with high-level languages (such as C, C++, or Pascal), you might think that HELLO.ASM is a bit long for a “Greetings, World!” program. Indeed, assembler programs tend to be much longer than high-level language programs because each high-level language statement actually breaks down to form many assembler instructions. However, assembly language gives you complete freedom over the actual instructions that are given to the computer’s CPU. With assembly language, you can write programs that tell the computer to do anything that it’s capable of doing.

**Assembling your first program**

Now that you’ve saved HELLO.ASM, you’ll want to run it. However, before you can run it, you’ll have to assemble it into an .OBJ file, and then link the file to form an executable program.

The assembly step turns your source code into an intermediate form called an **object module**, and the linking step combines one or more object modules into an executable program. You can do your assembling and linking from the command line.

To assemble HELLO.ASM, type the following line at the command line:

```plaintext
TASM hello
```

Unless you specify another file name, HELLO.ASM will be assembled to form the object file HELLO.OBJ. (Note that you don’t need to type in the file extension name; Turbo Assembler assumes all source files end with .ASM.) If you entered the HELLO.ASM program correctly, you’ll see a listing similar to the following one displayed onscreen:

```
Turbo Assembler Version 5.0 Copyright (c) 1988, 1996 by Borland International, Inc.
Assembling file: HELLO.ASM
Error messages: None
Warning messages: None
Passes: 1
Remaining memory: 439K
```

If you get warnings or errors, they are displayed with the program line numbers to indicate where they occurred. If you do get errors, edit HELLO.ASM make sure it’s
precisely the same as the program shown above. After editing the program, reassemble it with the TASM hello command.

**Linking your first program**

After you’ve successfully assembled HELLO.ASM, you’ll need to link the program using TLINK. At the command line, type:

```
TLINK hello
```

If no errors or warnings are reported, an executable file is created, named HELLO.EXE. To run this program, enter the command HELLO from the command line.

Errors can occur during the linking process, although it’s unlikely with this example program. If you do receive linker errors, modify your code to exactly match the code shown here, then assemble and link again.

**Recommended reading**

Although HELLO.ASM is a good program for testing TASM.EXE and TLINK.EXE, the example is of little use if you’re trying to learn assembly language. However, many books are available that teach both the fundamentals and the advanced features of assembly language. To help you get started with assembly language, refer to one or more of the following book titles:

In addition to these books, Intel Corporation offers fact sheets and reference manuals on the workings of their processor products. Contact Intel at the following address:

Using directives and switches

This chapter is dedicated to familiarizing you with Turbo Assembler's command-line options. We'll describe each of the command-line options you can use to alter the assembler's behavior, and then show how and when to use command files. We'll also describe the configuration file, and how you can control the display of warning and error messages.

Starting Turbo Assembler

If you start Turbo Assembler from your operating system command line without giving it any arguments, like this,

```
TASM
```

you'll get a screenful of help describing many of the command-line options, and the syntax for specifying the files you want to assemble. Figure 2.1 shows you how this looks.

Figure 2.1 Turbo Assembler command line

Turbo Assembler Version 4.1 Copyright (c) 1988, 1996 Borland International
/a,s Alphabetic or Source-code segment ordering
/c Generate cross-reference in listing
/dSYM=[VAL] Define symbol SYM = 0, or = value VAL
/e,r Emulated or Real floating-point instructions
/h,? Display this help screen
/iPATH Search PATH for include files
/jCMD Jam in an assembler directive CMD (e.g. /jIDEAL)
/k# Hash table capacity # symbols
/l, /la Generate listing: l=normal listing, la=expanded listing
/ml, /mx, /mu Case sensitivity on symbols: ml=all, mx=locals, mu=none
/m# Set maximum valid length for symbols
/m# Allow # multiple passes to resolve forward references
/n Suppress symbol tables in listing
/os,o/op,oi Object code: standard, standard w/overlays, Phar Lap, or IBM
/p Check for code segment overrides in protected mode
/q Suppress OBJ records not needed for linking
/t Suppress messages if successful assembly
/uxxxx Set version emulation, version xxxx
/w0/wl,w2 Set warning level: w0-none, w1=w2=warnings on
/w=xzx,wx=xxx Disable (-) or enable (+) warning xxx
/x Include false conditionals in listing
/z Display source line with error message
/zi/zd/zn Debug info: zi=full, zd=line numbers only, zn=none

With the command-line options, you can specify the name of one or more files that you want to assemble, as well as any options that control how the files get assembled.

The general form of the command line looks like this:

```
TASM fileset [; files]...
```

The semicolon (;) after the left bracket (l) lets you assemble multiple groups of files on one command line by separating the file groups. If you prefer, you can set different options for each set of files; for example,

```
TASM /e FILE1; /a FILE2
```

assembles FILE1.ASM with the /e command-line option and assembles file FILE2.ASM with the /a command-line option.

In the general form of the command line, fileset can be

```
[option] ... sourcefile [+] sourcefile ... 
[ , [objfile] , [listfile] , [xreffile] ]
```

This syntax shows that a group of files can start off with any options you want to apply to those files, followed by the files you want to assemble. A file name can be a single file name, or it can use the normal wildcard characters * and ? to specify multiple files to assemble. If your file name does not have an extension, Turbo Assembler adds the .ASM extension. For example, to assemble all the .ASM files in the current directory, you would type

```
TASM *
```

If you want to assemble multiple files, you can separate their names with the plus sign (+):

```
TASM MYFILE1 + MYFILE2
```

You can follow the file name you want to assemble by an optional object file name, listing file name, and a cross-reference file name. If you do not specify an object file or listing file, Turbo Assembler creates an object file with the same name as the source file and an extension of .OBJ.

A listing file is not generated unless you explicitly request one. To request one, place a comma after the object file name, followed by a listing file name. If you don’t explicitly provide a listing file name, Turbo Assembler creates a listing file with the same name as the source file and the extension .LST. If you supply a listing file name without an extension, .LST is appended to it.
A cross-reference file is not generated unless you explicitly request one. To request one, place a comma after the listing file name, followed by a cross-reference file name. If you don’t explicitly provide a cross-reference file name, Turbo Assembler creates a cross-reference file with the same name as the source file and the extension .XRF. If you supply a cross-reference file name without an extension, .XRF is appended to it. (TCREF, a cross-reference utility, is described on disk.)

If you want to accept the default object file name and also request a listing file, you must supply the comma that separates the object file name from the listing file name:

```
TASM FILE1,,TEST
```

This assembles FILE1.ASM to FILE1.OBJ and creates a listing file named TEST.LST.

If you want to accept the default object and listing file names and also request a cross-reference file, you must supply the commas that separate the file names:

```
TASM MYFILE,,MYXREF
```

This assembles file MYFILE.ASM to MYFILE.OBJ, with a listing in file MYFILE.LST and a cross-reference in MYXREF.XRF.

If you use wildcards to specify the source files to assemble, you can also use wildcards to indicate the object and listing file names. For example, if your current directory contains XX1.ASM and XX2.ASM, the command line

```
TASM XX*,YY*
```

assembles all the files that start with XX, generates object files that start with YY, and derives the remainder of the name from the source file name. The resulting object files are therefore called YY1.OBJ and YY2.OBJ.

If you don’t want an object file but you do want a listing file, or if you want a cross-reference file but don’t want a listing file or object file, you can specify the null device (NUL) as the file name. For example,

```
TASM FILE1,,NUL,
```

assembles file FILE1.ASM to object file FILE1.OBJ, doesn’t produce a listing file, and creates a cross-reference file FILE1.XRF.

## Command-line options

The command-line options let you control the behavior of the assembler, and how it outputs information to the screen, listing, and object file. Turbo Assembler provides you with some options that produce no action, but are accepted for compatibility with the current and previous versions of MASM:

- `/b` Sets buffer size
- `/v` Displays extra statistics

You can enter options using any combination of uppercase and lowercase letters. You can also enter your options in any order except where you have multiple `/i` or `/j` options; these are processed in sequence. When using the `/d` option, you must also be careful to define symbols before using them in subsequent `/d` options.
You can override command-line options by using conflicting directives in your source code.

Figure 2.1 on page 11 summarizes the Turbo Assembler command-line options; here’s a detailed description of each option.

### /a

**Function**
Specifies alphabetical segment-ordering

**Syntax**
/a

**Remarks**
The /a option tells Turbo Assembler to place segments in the object file in alphabetical order. This is the same as using the .ALPHA directive in your source file.

You usually only have to use this option if you want to assemble a source file that was written for very early versions of the IBM or Microsoft assemblers.

The /s option reverses the effect of this option by returning to the default sequential segment-ordering.

If you specify sequential segment-ordering with the .SEQ directive in your source file, it will override any /a you provide on the command line.

**Example**
```
TASM /a TEST1
```

This command line creates an object file, TEST1.OBJ, that has its segments in alphabetical order.

### /b

**Syntax**
/b

**Remarks**
The /b option is included for compatibility. It performs no action and has no effect on the assembly.

### /c

**Function**
Enables cross-reference in listing file

**Syntax**
/c

**Remarks**
The /c option enables cross-reference information in the listing file. Turbo Assembler adds the cross-reference information to the symbol table at the end of the listing file. This means that, in order to see the cross-reference information, you must either explicitly specify a listing file on the command line or use the /l option to enable the listing file.

For each symbol, the cross-reference shows the line on which it is defined and all lines that refer to it.

**Example**
```
TASM /l /c TEST1
```
This code creates a listing file that also has cross-reference information in the symbol table.

/d

Function
Defines a symbol

Syntax
/dsymbol=[value or expression]

Remarks
The /d option defines a symbol for your source file, exactly as if it were defined on the first line of your file with the = directive. You can use this option as many times as you want on the command line.

You can only define a symbol as being equal to another symbol or a constant value. You can’t use an expression with operators to the right of the equal sign (=). For example, /dX=9 and /dX=Y are allowed, but /dX=Y-4 is not.

Example
TASM /dMAX=10 /dMIN=2 TEST1

This command line defines two symbols, MAX and MIN, that other statements in the source file TEST1.ASM can refer to.

/e

Function
Generates floating-point emulator instructions

Syntax
/e

Remarks
The /e option tells Turbo Assembler to generate floating-point instructions that will be executed by a software floating-point emulator. Use this option if your program contains a floating-point emulation library that mimics the functions of the 80x87 numeric coprocessor.

Normally, you would only use this option if your assembler module is part of a program written in a high-level language that uses a floating-point emulation library. (Borland’s line of C++ compilers, Borland Pascal, Turbo Basic, and Turbo Prolog all support floating-point emulation.) You can’t just link an assembler program with the emulation library, since the library expects to have been initialized by the compiler’s startup code.

The /f option reverses the effect of this option by enabling the assembly of real floating-point instructions that can only be executed by a numeric coprocessor.

If you use the NOEMUL directive in your source file, it will override the /e option on the command line.

The /e command-line option has the same effect as using the EMUL directive at the start of your source file, and is also the same as using the /fEMUL command-line option.

Example
TASM /e SECANT
TCC -f TRIG.C SECANT.OBJ
The first command line assembles a module with emulated floating-point instructions. The second command line compiles a C source module with floating-point emulation and then links it with the object file from the assembler.

/h or /?

<table>
<thead>
<tr>
<th>Function</th>
<th>Displays a help screen</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/h or /?</td>
</tr>
<tr>
<td>Remarks</td>
<td>The /h option tells Turbo Assembler to display a help screen that describes the command-line syntax. This includes a list of the options, as well as the various file names you can supply. The /? option does the same thing.</td>
</tr>
<tr>
<td>Example</td>
<td>TASM /h</td>
</tr>
</tbody>
</table>

/i

<table>
<thead>
<tr>
<th>Function</th>
<th>Sets an include file path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/IPath</td>
</tr>
<tr>
<td>Remarks</td>
<td>The /i option lets you tell Turbo Assembler where to look for files that are included in your source file by using the INCLUDE directive. You can place more than one /i option on the command line (the number is only limited by RAM). When Turbo Assembler encounters an INCLUDE directive, the location where it searches for the include file is determined by whether the file name in the INCLUDE directive has a directory path or is just a simple file name. If you supply a directory path as part of the file name, that path is tried first, then Turbo Assembler searches the directories specified by /i command-line options in the order they appear on the command line. It then looks in any directories specified by /i options in a configuration file. If you don’t supply a directory path as part of the file name, Turbo Assembler searches first in the directories specified by /i command-line options, then it looks in any directories specified by /i options in a configuration file, and finally it looks in the current directory.</td>
</tr>
<tr>
<td>Example</td>
<td>TASM /i\INCLUDE /ID:\INCLUDE TEST1</td>
</tr>
</tbody>
</table>

If the source file contains the statement

```
INCLUDE MYMACS.INC
```

Turbo Assembler will first look for \INCLUDE\MYMACS.INC, then it will look for D:\INCLUDE\MYMACS.INC. If it still hasn’t found the file, it will look for MYMACS.INC in the current directory. If the statement in your source file had been

```
INCLUDE INC\MYMACS.INC
```

16 Turbo Assembler User's Guide
Turbo Assembler would first look for INCS\MYMACS.INC and then it would look for \INCLUDE\MYMACS.INC, and finally for D:INCLUDE\MYMACS.INC.

\[j\]

**Function**
Defines an assembler startup directive

**Syntax**
\(/j \text{directive}\)

**Remarks**
The \(/j\) option lets you specify a directive that will be assembled before the first line of the source file. \text{directive} can be any Turbo Assembler directive that does not take any arguments, such as \text{.286}, \text{IDEAL}, \%\text{MACS}, \text{NOJUMPS}, and so on.

You can put more than one \(/j\) option on the command line; they are processed from left to right across the command line.

**Example**
\text{TASM /j.286 /jIDEAL TEST1}

This code assembles the file TEST1.ASM with 80286 instructions enabled and Ideal mode expression-parsing enabled.

\[k\]

**Function**
Sets the maximum number of symbols allowed

**Syntax**
\(/k h \text{symbols}\)

**Remarks**
The \(/k h\) option sets the maximum number of symbols that your program can contain. If you don't use this option, your program can only have a maximum of 8,192 symbols; using this option increases the number of symbols to \text{nsymbols}, up to a maximum of 32,768.

Use this option if you get the \text{Out of hash space} message when assembling your program.

You can also use this option to reduce the total number of symbols below the default 8,192. This releases some memory that can be used when you are trying to assemble a program but don't have enough available memory.

**Example**
\text{TASM /kh100000 BIGFILE}

This command tells Turbo Assembler to reserve space for 10,000 symbols when assembling the file BIGFILE.

\[l\]

**Function**
Generates a listing file

**Syntax**
\(/l\)
### /la

**Function**
Shows high-level interface code in listing file

**Syntax**
/la

**Remarks**
The /la option tells Turbo Assembler to show all generated code in the listing file, including the code that gets generated as a result of the high-level language interface .MODEL directive.

**Example**
TASM /la FILE1

### /m

**Function**
Sets the maximum number of assembly passes

**Syntax**
/m [npasses]

**Remarks**
Normally, Turbo Assembler functions as a single-pass assembler. The /m option lets you specify the maximum number of passes the assembler should make during the assembly process. TASM automatically decides whether it can perform less than the number of passes specified. If you select the /m option, but don't specify npasses, a default of five is used.

You might want to specify multiple passes either if you want Turbo Assembler to remove NOP instructions added because of forward references or if you are assembling a module containing instructions that require two passes. If multiple passes are not enabled, such a module will produce at least one “Pass-dependent construction encountered” warning. If the /m option is enabled, Turbo Assembler assembles this module correctly but will not optimize the code by removing NOPs, no matter how many passes are allowed. The warning “Module is pass dependent—compatibility pass was done” is displayed if this occurs.

**Example**
TASM /m2 TEST1

This tells Turbo Assembler to use up to two passes when assembling TEST1.

### /ml

**Function**
Treats symbols as case-sensitive

**Syntax**
/ml
Remarks    The /ml option tells Turbo Assembler to treat all symbol names as case-sensitive. Normally, uppercase and lowercase letters are considered equivalent so that the names ABCxyz, abcxyz, and ABCXYZ would all refer to the same symbol. If you specify the /ml option, these three symbols will be treated as distinct. Even when you specify /ml, you can still enter any assembler keyword in uppercase or lowercase. Keywords are the symbols built into the assembler that have special meanings, such as instruction mnemonics, directives, and operators.

Example    TASM /ml TEST1

where TEST1.ASM contains the following statements:

```asm
abc DW 0
ABC DW 1   ;not a duplicate symbol
Mov Ax,[Bp] ;mixed case OK in keywords
```

The /ml switch used together with /mx has a special meaning for Pascal symbols. See the /mx section for further details.

/mu

Function    Converts symbols to uppercase

Syntax      /mu

Remarks     The /mu option tells Turbo Assembler to ignore the case of all symbols. By default, Turbo Assembler specifies that any lowercase letters in symbols will be converted to uppercase unless you change it by using the /ml directive.

Example     TASM /mu TEST1

makes sure that all symbols are converted to uppercase (which is the default):

```asm
EXTRN myfunc:NEAR
call myfunc       ;don't know if declared as
                 ; MYFUNC, Myfunc,...
```

/mv#

Function    Sets the maximum length of symbols.

Syntax      /mv#

Remarks     The /mv# option sets the maximum length of symbols that TASM will distinguish between. For example, if you set /mv12, TASM will see ABCDEFGHIJKLMNOP and ABCDEFGHIJKLMNOP as the same symbol, but not ABCDEFGHIJKLMNOP. Note that the minimum number you can have here is 12.

/mx

Function    Makes public and external symbols case-sensitive
Syntax /mx.
Remarks The /mx option tells Turbo Assembler to treat only external and public symbols as case-sensitive. All other symbols used (within the source file) are treated as uppercase.

You should use this directive when you call routines in other modules that were compiled or assembled so that case-sensitivity is preserved; for example, modules compiled by one of Borland’s line of C++ compilers.

Example TASM /mx TEST1;

where TEST1.ASM contains the following source lines:

```
EXTRN Cfunc:Near
myproc PROC Near
call Cfunc
```

Note Using the /mx and /ml options together has a special meaning for symbols declared as Pascal; if you use these symbols together, the symbols will be published as all uppercase to the linker.

Function Suppresses symbol table in listing file
Syntax /n
Remarks The /n option indicates that you don’t want the usual symbol table at the end of the listing file. Normally, a complete symbol table listing appears at the end of the file, showing all symbols, their types, and their values.

You must specify a listing file, either explicitly on the command line or by using the /l option; otherwise, /n has no effect.

Example TASM /l /n TEST1

This code generates a listing file showing the generated code only, and not the value of your symbols.

Function Generates overlay code for TLINK
Syntax /o
Remarks Specifying the /o switch on the command line causes overlay-compatible fixups to be generated. When this switch is used, 386 references to USE32 segments should not be made since they won’t link properly.
### /oi

<table>
<thead>
<tr>
<th>Function</th>
<th>Generates overlay code for the IBM linker</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/o</td>
</tr>
<tr>
<td>Remarks</td>
<td>Specifying the /oi switch on the command will generate overlay-compatible fixups for the IBM linker. The resulting object file will not be compatible with TLINK, Borland's linker.</td>
</tr>
</tbody>
</table>

### /op

<table>
<thead>
<tr>
<th>Function</th>
<th>Generates overlay code for the Phar Lap linker</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/op</td>
</tr>
<tr>
<td>Remarks</td>
<td>Specifying the /op switch on the command will generate overlay-compatible fixups for the Phar Lap linker. The resulting object file will not be compatible with TLINK, Borland's linker.</td>
</tr>
</tbody>
</table>

### /os

<table>
<thead>
<tr>
<th>Function</th>
<th>Outputs TLINK-compatible objects without overlay support. This is the default selection.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/os</td>
</tr>
<tr>
<td>Remarks</td>
<td>Specifying the /os switch on the command will generate objects without overlay support for use with TLINK.</td>
</tr>
</tbody>
</table>

### /p

<table>
<thead>
<tr>
<th>Function</th>
<th>Checks for impure code in protected mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>/p</td>
</tr>
<tr>
<td>Remarks</td>
<td>The /p option specifies that you want to be warned about any instructions that generate “impure” code in protected mode. Instructions that move data into memory by using a CS: override in protected mode are considered impure because they might not work correctly unless you take special measures. You only need to use this option if you are writing a program that runs in protected mode on the 80286, 386, or i486.</td>
</tr>
<tr>
<td>Example</td>
<td>TASM /p TEST1</td>
</tr>
</tbody>
</table>

where TEST1.ASM contains the following statements:
### /q

**Function**  
Suppresses .OBJ records not needed for linking

**Syntax**  
/q

**Remarks**  
The `/q` option removes the copyright and file dependency records from the resulting .OBJ files, making it smaller. Don’t use this option if you are using MAKE or a similar program that relies on the dependency records.

### /r

**Function**  
Generates real floating-point instructions

**Syntax**  
/r

**Remarks**  
The `/r` option tells Turbo Assembler to generate real floating-point instructions (instead of generating emulated floating-point instructions). Use this option if your program is going to run on machines equipped with an 80x87 numeric coprocessor.

The `/e` option reverses the effect of this option in generating emulated floating-point instructions.

If you use the `EMUL` directive in your source file, it will override the `/r` option on the command line.

The `/r` command-line option has the same effect as using the `NOEMUL` directive at the start of your source file, and is also the same as using the `/jNOEMUL` command-line option.

**Example**  
TASM /r SECANT  
TFC /$N+ /$E TRIG.PAS

The first command line assembles a module with real floating-point instructions. The second compiles a Pascal source module with real floating-point instructions that links in the object file from the assembler.

### /S

**Function**  
Specifies sequential segment-ordering

**Syntax**  
/s

**Remarks**  
The `/s` option tells Turbo Assembler to place segments in the object file in the order in which they were encountered in the source file. By default, Turbo Assembler uses segment-ordering, unless you change it by placing an `/a` option in the configuration file.
If you specify alphabetical segment-ordering in your source file with the .ALPHA directive, it will override /s on the command line.

Example TASM /s TEST1

This code creates an object file (TEST1.OBJ) that has its segments ordered exactly as they were specified in the source file.

/t

Function Suppresses messages on successful assembly
Syntax /t
Remarks The /t option stops any display by Turbo Assembler unless warning or error messages result from the assembly.
You can use this option when you are assembling many modules, and you only want warning or error messages to be displayed onscreen.
Example TASM /t TEST1

/u

Function Sets version ID in command line
Syntax /u version
Remarks The /u option lets you specify which version of Turbo Assembler or MASM you want to use to run your modules. This is the command-line version of the VERSION directive.

/utthk

Function Enables support for Windows 95 flat thunking.
Syntax /utthk
Remarks The /utthk option tells Turbo Assembler to assemble code generated by the Microsoft thunk compiler. For more information, see the thunking example and documentation provided in the \EXAMPLES\THUNK95 directory off your main TASM directory.

/v

Syntax /v
Remarks The /v option is included for compatibility. It performs no action and has no effect on the assembly.
Function Controls the generation of warning messages

Syntax

/w

w-[warnclass]
w+[warnclass]

Remarks The /w option controls which warning messages are emitted by Turbo Assembler.

If you specify /w by itself, “mild” warnings are enabled. Mild warnings merely indicate that you can improve some aspect of your code’s efficiency.

If you specify /w- without warnclass, all warnings are disabled. If you follow /w- with warnclass, only that warning is disabled. Each warning message has a three-letter identifier:

- ALN Segment alignment
- ASS Assuming segment is 16-bit
- BRK Brackets needed
- GTP Global type doesn’t match symbol type
- ICG Inefficient code generation
- INT INT 3 generation
- LCO Location counter overflow
- MCP MASM compatibility pass
- OPI Open IF conditional
- OPP Open procedure
- OPS Open segment
- OVF Arithmetic overflow
- PDC Pass-dependent construction
- PQK Assuming constant for [const] warning
- PRO Write-to memory in protected mode needs CS override
- RES Reserved word warning
- TPI illegal warning
- UNI For turning off uninitialized segment warning

If you specify /w+ without warnclass, all warnings are enabled. If you specify /w+ with warnclass from the preceding list, only that warning will be enabled.

By default, Turbo Assembler first starts assembling your file with all warnings enabled except the inefficient code-generation (ICG) and the write-to-memory in protected mode (PRO) warnings.

You can use the WARN and NOWARN directives within your source file to control whether a particular warning is allowed for a certain range of source lines. These directives are described later in this chapter.

Example TASM /w TEST1
The following statement in TEST1.ASM issues a warning message that would not have appeared without the /w option:

```
mov bx,ABC  ;inefficient code generation warning
ABC = 1
```

With the command line

```
TASM /w-ovf TEST2
```

no warnings are generated if TEST2.ASM contains

```
dw 1000h * 20h
```

---

**/x**

**Function** Includes false conditionals in listing

**Syntax** /x

**Remarks** If a conditional IF, IFNDEF, IFDEF, and so forth evaluates to False, the /x option causes the statements inside the conditional block to appear in the listing file. This option also causes the conditional directives themselves to be listed; normally they are not. You must specify a listing file on the command line or use the /l option, otherwise /x has no effect.

You can use the .LFCOND, .SFCOND, and .TFCOND directives to override the effects of the /x option.

**Example** TASM /x TEST1

---

**/z**

**Function** Displays source lines along with error messages

**Syntax** /z

**Remarks** The /z option tells Turbo Assembler to display the corresponding line from the source file when an error message is generated. The line that caused the error is displayed before the error message. With this option disabled, Turbo Assembler just displays a message that describes the error.

**Example** TASM /z TEST1

---

**/zd**

**Function** Enables line-number information in object files

**Syntax** /zd

**Remarks** The /zd option causes Turbo Assembler to place line-number information in the object file. This lets the debugger display the current location in your source code, but does not
put the information in the object file that would allow the debugger to access your data items.

If you run out of memory when trying to debug your program, you can use /zd for some modules and /zi for others.

Example TASM /zd TEST1

/zi

**Function** Enables debug information in object file

**Syntax** /zi

**Remarks** The /zi option tells Turbo Assembler to output complete debugging information to the object file. This includes line-number records to synchronize source code display and data type information to let you examine and modify your program’s data.

The /zi option lets you use all the features of the debugger to step through your program and examine or change your data items. You can use /zi on all your program’s modules, or just on those you’re interested in debugging. Since the /zi switch adds information to the object and executable programs, you might not want to use it on all your modules if you run out of memory when running a program under the debugger.

Example TASM .zi TEST1

/zn

**Function** Disables debug information in object file

**Syntax** /zn

**Remarks** The /zn option tells Turbo Assembler to disable the output of debugging information to the object file. It’s useful for overriding any prevailing /zi switch in a configuration file.

**Indirect command files**

At any point when entering a command line, Turbo Assembler lets you specify an *indirect* command file by preceding its name with an “at” sign (@). For example,

```
TASM /dTESTMODE @MYPROJ.TA
```

causes the contents of the file MYPROJ.TA to become part of the command line, exactly as if you had typed in its contents directly.

This useful feature lets you put your most frequently used command lines and file lists in a separate file. And you don’t have to place your entire command line in one indirect file, since you can use more than one indirect file on the command line and can also mix indirect command files with normal arguments. For example,

```
TASM @MYFILES @IOLIBS /dbuf=1024
```
This way you can keep long lists of standard files and options in files, so that you can quickly and easily alter the behavior of an individual assembly run.

You can either put all your file names and options on a single line in the command file, or you can split them across as many lines as you want.

The configuration file

Turbo Assembler also lets you put your most frequently used options into a configuration file in the current directory. This way, when you run Turbo Assembler, it looks for a file called TASM.CFG in your current directory. If Turbo Assembler finds the file, it treats it as an indirect file and processes it before anything else on the command line.

This is helpful when you have all the source files for a project in a single directory, and you know that, for example, you always want to assemble with emulated floating-point instructions (the /e option). You can place that option in the TASM.CFG file, so you don’t have to specify that option each time you start Turbo Assembler.

The contents of the configuration file have exactly the same format as an indirect file. The file can contain any valid command-line options, on as many lines as you want. The options are treated as if they all appeared on one line.

The contents of the configuration file are processed before any arguments on the command line. This lets you override any options set in the configuration file by simply placing an option with the opposite effect on the command line. For example, if your configuration file contains

```
/a /e
```

and you invoke Turbo Assembler with

```
TASM /s /r MYFILE
```

MYFILE is your program file, and your file will be assembled with sequential segment-ordering (/s) and real floating-point instructions (/r), even though the configuration file contained the /a and /e options that specified alphabetical segment-ordering and emulated floating-point instructions.
General programming concepts

This chapter introduces you to the basic concepts of Turbo Assembler. We'll look at Ideal mode versus MASM mode, commenting your programs and extending lines of code, including files, using predefined symbols, and using several important directives that produce module information. Although this is a lot of ground to cover, it will give you a good idea of what assembly language is all about.

Turbo Assembler Ideal mode

For those of you struggling to make MASM do your bidding, this may be the most important chapter in the manual. In addition to near-perfect compatibility with MASM syntax, Turbo Assembler smooths the rough areas of assembly language programming with a MASM derivative we call Ideal mode.

Among other things, Ideal mode lets you know solely by looking at the source text exactly how an expression or instruction operand will behave. There's no need to memorize all of MASM's many quirks and tricks. Instead, with Ideal mode, you write clear, concise expressions that do exactly what you want.

Ideal mode uses nearly all MASM's same keywords, operators, and statement constructions. This means you can explore Ideal mode's features one at a time without having to learn a large number of new rules or keywords.

Ideal mode adds strict type checking to expressions. Strict type checking helps reduce errors caused by assigning values of wrong types to registers and variables, and by using constructions that appear correct in the source text, but are assembled differently than you expect. Instead of playing guessing games with values and expressions, you can use Ideal mode to write code that makes logical and aesthetic sense.

With strict type checking, Ideal mode expressions are both easier to understand and less prone to producing unexpected results. And, as a result, many of the MASM idiosyncrasies we warn you about in other chapters disappear.
Ideal mode also has a number of features that make programming easier for novices and experts alike. These features include the following:

- duplicate member names among multiple structures
- complex HIGH and LOW expressions
- predictable EQU processing
- correct handling of grouped data segments
- improved consistency among directives
- sensible bracketed expressions

Why use Ideal mode?

There are many good reasons why you should use Turbo Assembler's Ideal mode. If you are just learning assembly language, you can easily construct Ideal mode expressions and statements that have the effects you desire. You don’t have to experiment trying different things until you get an instruction that does what you want. If you are an experienced assembly language programmer, you can use Ideal mode features to write complex programs using language extensions such as nestable structures and unions.

As a direct benefit of cleaner syntax, Ideal mode assembles files 30% faster than MASM mode. The larger your projects and files, the more savings in assembly time you’ll gain by switching to Ideal mode.

Strong type-checking rules, enforced by Ideal mode, let Turbo Assembler catch errors that you would otherwise have to find at run time or by debugging your code. This is similar to the way high-level language compilers point out questionable constructions and mismatched data sizes.

Although Ideal mode uses a different syntax for some expressions, you can still write programs that assemble equally well in both MASM and Ideal modes. You can also switch between MASM and Ideal modes as often as necessary within the same source file. This is especially helpful when you’re experimenting with Ideal mode features, or when you’re converting existing programs written in the MASM syntax. You can switch to Ideal mode for new code that you add to your source files and maintain full MASM compatibility for other portions of your program.

Entering and leaving Ideal mode

Use the IDEAL and MASM directives to switch between Ideal and MASM modes. Turbo Assembler always starts assembling a source file in MASM mode. To switch to Ideal mode, include the IDEAL directive in your source file before using any Ideal mode capabilities. From then on, or until the next MASM directive, all statements behave as described in this chapter. You can switch back and forth between MASM and Ideal modes in a source file as many times as you wish and at any place. Here's a sample:

```
DATA SEGMENT
abc LABEL BYTE
xyz DW 0
DATA ENDS
```
In Ideal mode, directive keywords such as PROC and SEGMENT appear before the identifying symbol names, which is the reverse of MASM’s order. You also have the option of repeating a segment or procedure name after the ENDP and ENDS directives. Adding the name can help clarify the program by identifying the segment or procedure that is ending. This is a good idea, especially in programs that nest multiple segments and procedures. You don’t have to include the symbol name after ENDP and ENDS, however.

### MASM and Ideal mode differences

This section describes the main differences between Ideal and MASM modes. If you know MASM, you might want to experiment with individual features by converting small sections of your existing programs to Ideal mode. Further details of these differences are in Chapter 5, “Using expressions and symbol values.”

### Expressions and operands

The biggest difference between Ideal and MASM mode expressions is the way square brackets function. In Ideal mode, square brackets always refer to the contents of the enclosed quantity. Brackets never cause implied additions to occur. Many standard MASM constructions, therefore, are not permitted by Ideal mode.

In Ideal mode, square brackets must be used in order to get the contents of an item. For example,

```
mov ax, wordptr
```

displays a warning message. You’re trying to load a pointer (wordptr) into a register (AX). The correct form is

```
mov ax, [wordptr]
```

Using Ideal mode, it’s clear you are loading the contents of the location addressed by wordptr (in the current data segment at DS) into AX.
If you wish to refer to the offset of a symbol within a segment, you must explicitly use the OFFSET operator, as in this example:

\[ \text{mov ax,OFFSET wordptr} \]

**Operators**

The changes made to the expression operators in Ideal mode increase the power and flexibility of some operators while leaving unchanged the overall behavior of expressions. The precedence levels of some operators have been changed to facilitate common operator combinations.

The period (.) structure member operator is far more strict in Ideal mode when accurately specifying the structure members you’re referring to. The expression to the left of a period *must* be a structure pointer. The expression to the right *must* be a member name in that structure. Here’s an example of loading registers with the values of specific structure members:

\[ ;\text{Declare variables using the structure types} \]
\[ S\_Stuff SomeStuff <> \]
\[ O\_Stuff OtherStuff <> \]
\[ \text{mov ax,}[S\_Stuff.Amount] \quad ;\text{load word value} \]
\[ \text{mov bl,}[O\_Stuff.Amount] \quad ;\text{load byte value} \]

**Suppressed fixups**

Turbo Assembler in Ideal mode does not generate segment-relative fixups for private segments that are page- or paragraph-aligned. Because the linker does not require such fixups, assembling programs in Ideal mode can result in smaller object files that also link more quickly than object files generated by MASM mode. The following demonstrates how superfluous fixups occur in MASM but not in Ideal mode:

\[ \text{SEGMENT DATA PRIVATE PARA} \]
\[ \text{VAR1 DB 0} \]
\[ \text{VAR2 DW 0} \]
\[ \text{ENDS} \]
\[ \text{SEGMENT CODE} \]
\[ \text{ASSUME ds:DATA} \]
\[ \text{mov ax,VAR2} \quad ;\text{no fixup needed} \]
\[ \text{ENDS} \]

**Note** This difference has no effect on code that you write. The documentation here is simply for your information.

**Operand for BOUND instruction**

The BOUND instruction expects a WORD operand, not a DWORD. This lets you define the lower and upper bounds as two constant words, eliminating the need to convert the operand to a DWORD with an explicit DWORD PTR. In MASM mode, you must write

\[ \text{BOUNDS DW 1,4} \quad ;\text{lower and upper bounds} \]
\[ \text{BOUND AX, DWORD PTR BOUNDS} \quad ;\text{required for MASM mode} \]

but in Ideal mode, you need only write
Segments and groups

The way Turbo Assembler handles segments and groups in Ideal mode can make a difference in getting a program up and running. If you're like most people, you probably shudder at the thought of dealing with a bug that has anything to do with the interaction of segments and groups.

Much of the difficulty in this process stems from the arbitrary way that MASM and, therefore, Turbo Assembler's MASM mode, makes assumptions about references to data or code within a group. Fortunately, Ideal mode alleviates some of the more nagging problems caused by MASM segment and group directives, as you'll see in the information that follows.

Accessing data in a segment belonging to a group

In Ideal mode, any data item in a segment that is part of a group is considered to be principally a member of the group, not of the segment. An explicit segment override must be used for Turbo Assembler to recognize the data item as a member of the segment.

MASM mode handles this differently; sometimes a symbol is considered to be part of the segment instead of the group. In particular, MASM mode treats a symbol as part of a segment when the symbol is used with the OFFSET operator, but as part of a group when the symbol is used as a pointer in a data allocation. This can be confusing because when you directly access the data without OFFSET, MASM incorrectly generates the reference relative to the segment instead of the group.

Here's an example of how easily you can get into trouble with MASM's addressing quirks. Consider the following incomplete MASM program, which declares three data segments:

```
    dseg1 SEGMENT PARA PUBLIC 'data'
    v1 DB 0
    dseg1 ENDS

    dseg2 SEGMENT PARA PUBLIC 'data'
    v2 DB 0
    dseg2 ENDS

    dseg3 SEGMENT PARA PUBLIC 'data'
    v3 DB 0
    dseg3 ENDS

    DGROUP GROUP dseg1,dseg2,dseg3
    cseg SEGMENT PARA PUBLIC 'code'
        ASSUME cs:cseg,ds:DGROUP
    start:
```
The three segments, dseg1, dseg2, and dseg3, are grouped under one name, DGROUP. As a result, all the variables in the individual segments are stored together in memory. In the program source text, each of the individual segments declares a BYTE variable, labeled v1, v2, and v3.

In the code portion of this MASM program, the offset addresses of the three variables are loaded into registers AX, BX, and CX. Because of the earlier ASSUME directive and because the data segments were grouped together, you might think that MASM would calculate the offsets to the variables relative to the entire group in which the variables are eventually stored in memory.

But this is not what happens. Despite your intentions, MASM calculates the offsets of the variables relative to the individual segments, dseg1, dseg2, and dseg3. It does this even though the three segments are combined into one data segment in memory, addressed here by register DS. It makes no sense to take the offsets of variables relative to individual segments in the program text when those segments are combined into a single segment in memory. The only way to address such variables is to refer to their offsets relative to the entire group.

To fix the problem in MASM, you must specify the group name along with the OFFSET keyword:

```asm
mov ax,OFFSET DGROUP:v1
mov bx,OFFSET DGROUP:v2
mov cx,OFFSET DGROUP:v3
```

Although this now assembles correctly and loads the offsets of v1, v2, and v3 relative to DGROUP (which collects the individual segments), you might easily forget to specify the DGROUP qualifier. If you make this mistake, the offset values will not correctly locate the variables in memory and you’ll receive no indication from MASM that anything is amiss. In Ideal mode, there’s no need to go to all this trouble:

```asm
IDEAL
SEGMENT dseg1 PARA PUBLIC 'data'
v1   DB 0
ENDS

SEGMENT dseg2 PARA PUBLIC 'data'
v2   DB 0
ENDS

SEGMENT dseg3 PARA PUBLIC 'data'
v3   DB 0
ENDS

GROUP DGROUP dseg1,dseg2,dseg3
SEGMENT cseg PARA PUBLIC 'code'
ASSUME cs:cseg, ds:DGROUP
```
The offsets to $v1$, $v2$, and $v3$ are correctly calculated relative to the group that collects the individual segments to which the variables belong. Ideal mode does not require the \texttt{DGROUP} qualifier to refer to variables in grouped segments. MASM mode does require the qualifier and, even worse, gives no warning of a serious problem should you forget to specify the group name in every single reference.

**Commenting the program**

Commenting your code is a great way to help you (or anyone who has to maintain your code in the future) quickly understand how it functions. Using comments is good programming practice in any language. They can describe the semantic as opposed to syntactic function of your code. We recommend that you use comments liberally in your Turbo Assembler code, and this section describes how you can do so.

**Comments at the end of the line**

There are several ways to comment assembler code. One approach is to add a comment at the end of a line using the semicolon (;), such as

\begin{verbatim}
mov [bx], al ; store the modified character
\end{verbatim}

Another way to comment assembler code is to use the line continuation character (\textbackslash) as a comment character. See the section called “Extending the line” for an example of how this is done.

**The \texttt{COMMENT} directive**

The \texttt{COMMENT} directive lets you comment blocks of code. \texttt{COMMENT} ignores all text from the first delimiter character and the line containing the next occurrence of the delimiter. The following example uses * as a delimiter character:

\begin{verbatim}
COMMENT *
    Work long and late to get free pizza
*
\end{verbatim}

\textbf{Note} \texttt{COMMENT} only works in MASM mode.
Extending the line

For lines of code that are longer than 80 characters, Turbo Assembler provides the \ line continuation character. Use this character at the end of your line, because Turbo Assembler ignores any characters that follow it on the same line.

The maximum line length is 1024 when you use \; however, tables, records, and enums might have definitions that are longer than 1024 characters. An alternative that does not have the 1024 character limitation is the multiline definition syntax. Here's an example of the syntax (for an enum definition):

```plaintext
foo enum {   ;Multiline version
    f1
    f2
    f3
    f4
    f5
    f6
    f7
    f8
}
```

A more compact version of the same definition:

```plaintext
foo enum f1,f2,{   ; Compact multiline version
    f3,f4
    f5,f6
    f7,f8
}
```

When using multiline definitions, remember these rules:

- The left brace that starts the definition must be the last token on the starting line. It does not, however, have to precede the first element in the list.

- You cannot include any directives such as IF or INCLUDE inside the multiline definition.

MASM-mode line continuation is available if you select VERSION M510, M520. Strings and other tokens can be extended across multiple lines if the "\" character is the last character on the line. For example,

```plaintext
VERSION M510
DB 'Hello out there   
    you guys'
```

You can place standard Turbo Assembler mode line continuation anywhere in a line, and it is always available. It functions as a comment as well. For example,

```plaintext
ARG a1:word,   \first argument
    a2:word,   \second argument
    a3:word    ;final argument
```
Using INCLUDE files

Include files let you use the same block of code in several places in your program, insert the block in several source modules, or reduce the size of your source program without having to create several linkable modules. Using the INCLUDE directive tells Turbo Assembler to find the specified files on disk and assemble them as if they were a part of the source program.

The Ideal mode syntax:

```
INCLUDE "filename"
```

The MASM mode syntax:

```
INCLUDE filename
```

Note You can nest INCLUDE directives as deep as you want.

`filename` can specify any drive, directory, or extension. If `filename` does not include a directory or drive name, Turbo Assembler first searches for the file in any directories you specify with the `/I` command-line option, and then in the current directory.

Predefined symbols

Turbo Assembler provides a number of predefined symbols that you can use in your programs. These symbols can have different values at different places in your source file, and are similar to equated symbols you define using the EQU directive. When Turbo Assembler encounters one of these symbols in your source file, it replaces it with the current value of that predefined symbol.

Some of these symbols are text (string) equates, some are numeric equates, and others are aliases. The string values can be used anywhere that you would use a character string, for example, to initialize a series of data bytes using the DB directive:

```
NOW DB ??time
```

Numeric predefined values can be used anywhere that you would use a number:

```
-IF ??version GT 100h
```

Alias values make the predefined symbol into a synonym for the value it represents, allowing you to use the predefined symbol name anywhere you would use an ordinary symbol name:

```
ASSUME cs:@code
```

All the predefined symbols can be used in both MASM and Ideal mode.

If you use the `/ml` command-line option when assembling, you must use the predefined symbol names exactly as they are described on the following pages.

Note The following rule applies to predefined symbols starting with an at-sign (@): *The first letter of each word that makes up part of the symbol name is an uppercase letter (except for segment names); the rest of the word is lowercase.* As an example,

```
@FileName
```
Notice that @FileName performs an alias equate for the current assembly line.

The exception is redefined symbols, which refer to segments. Segment names begin with an at-sign (@) and are all lowercase. For example,

```plaintext
@curseg
@fardata
```

For symbols that start with two question marks (??), the letters are all lowercase. For example,

```plaintext
??date
??version
```

Note that the ??date symbol defines a text equate that represents today’s date. The exact format of the date string is determined by the country code. The ??version symbol lets you write source files that can take advantage of features in particular versions of Turbo Assembler. This equate also lets your source files know whether they are being assembled by MASM or Turbo Assembler, since ??version is not defined by MASM. Similarly, ??filename defines an eight-character string that represents the file name being assembled. The file name is padded with spaces if it contains fewer than eight characters. The ??time symbol defines a text equate that represents the current time. The exact format of the time string is determined by the country code.

## Assigning values to symbols

Turbo Assembler provides two directives that let you assign values to symbols: EQU and =. The EQU directive defines a string, alias, or numeric equate. To use it, specify the following syntax,

```plaintext
name EQU expression
```

where `name` is assigned the result of evaluating `expression`. `name` must be a new symbol name that you haven’t previously defined in a different manner. In MASM mode, you can only redefine a symbol that you defined using the EQU directive if you first define it as a string equate. In MASM mode, EQU can generate any one of three kinds of equates: alias, expression, or string.

The = directive defines only a numeric equate. To use it, specify

```plaintext
name = expression
```

where `name` is assigned the result of evaluating `expression`, which must evaluate to either a constant or an address within a segment. `name` can either be a new symbol name, or a symbol that you previously defined with =. Since the = directive has far more predictable behavior than the EQU directive in MASM mode, use = instead of EQU wherever you can.

## General module structure

Turbo Assembler provides several directives to help you work with modules of code. The remainder of this chapter describes these directives.
The VERSION directive

Using the VERSION directive lets you specify which version of Turbo Assembler or MASM you've written particular modules for. This is helpful for upward and downward compatibility of various versions of TASM and MASM. The VERSION directive also puts you into the operating mode for the specified version.

You can specify the VERSION directive as either a command-line switch or within program source code.

Within code, the syntax is

```
VERSION <version_ID>
```

You can specify the following legal version IDs:

- M400  MASM 4.0
- M500  MASM 5.0
- M510  MASM 5.1
- M520  MASM 5.2 (Quick ASM)
- 100   Turbo Assembler 1.0
- T101  Turbo Assembler 1.01
- T200  Turbo Assembler 2.0
- T250  Turbo Assembler 2.5
- T300  Turbo Assembler 3.0
- T310  Turbo Assembler 3.1
- T320  Turbo Assembler 3.2
- T400  Turbo Assembler 4.0
- T410  Turbo Assembler 4.1
- T500  Turbo Assembler 5.0

The command-line syntax is:

```
/UV<version_ID>
```

As an example, if you wanted to assemble a program written for MASM 5.0, you could leave the source for the program intact and use the switch `/uM510`.

Here are the general rules:

1. The VERSION directive always selects MASM mode by default, because that is the starting mode of operation for both MASM and Turbo Assembler.
2. The VERSION directive limits the high-priority keywords available to those in the specified compiler and version. As a result, some features that were added to later versions are unavailable to you.
3. From Ideal mode, the VERSION directive is unavailable if you select a version prior to T300. To use the VERSION directive in this case, you must switch to MASM mode first.
4. No attempt is made to limit access to low priority keywords, since these will not affect compatibility.
Previous versions of Turbo Assembler controlled MASM compatibility with directives such as MASM51, NOMASM51, QUIRKS, SMART, and NOSMART. The VERSION directive supersedes these older directives. See Appendix B for a complete list of keywords available with each prior version of Turbo Assembler.

The NAME directive
Use the NAME directive to set the object file’s module name. Here is the syntax for it:

    NAME modulename

Turbo Assembler usually uses the source file name with any drive, directory, or extension as the module name. Use NAME if you wish to change this default name; modulename will be the new name of the module. For example,

    NAME loader

Note: The NAME directive only works in Ideal mode.

The END directive
Use the END directive to mark the end of your source file. The syntax looks like this:

    END [ startaddress ]

startaddress is an optional symbol or expression that specifies the address in your program where you want execution to begin. If your program is linked from multiple source files, only one file can specify a startaddress. startaddress can be an address within the module; it can also be an external symbol defined in another module, declared with the EXTRN directive.

Turbo Assembler ignores any text after the END directive in the source file.

Example

```assembly
.MODEL small
.CODE
.START:
;Body of program goes here
END START ;program entry point is "START"
.THE LINE IS IGNORED
SO IS THIS ONE
```

Displaying a message during assembly

Turbo Assembler provides two directives that let you display a string on the console during assembly: DISPLAY and %OUT. You can use these directives to report on the progress of an assembly, either to let you know how far the assembly has progressed, or to let you know that a certain part of the code has been reached.

The two directives are essentially the same except that DISPLAY displays a quoted string onscreen, and %OUT displays a nonquoted string onscreen.

In both Ideal and MASM modes, the syntax for DISPLAY is

```
DISPLAY "text"
```
where \textit{text} is any message you want to display.

The syntax for \%OUT in both Ideal and MASM modes is

\%OUT text

where, again, \textit{text} is the message that you want displayed.

## Displaying warning messages

Turbo Assembler lets you choose what (if any) warning messages you’ll receive when you assemble different parts of your code. Each warning message contains a three-letter identifier, which you can specify ahead of time to let the assembler know whether or not you want to see warnings of that kind. You can use the \texttt{WARN} directive to enable warning messages, and the \texttt{NOWARN} directive to disable them.

The syntax of the \texttt{WARN} directive is

\texttt{WARN [warnclass]}

where \texttt{warnclass} is the three-letter identifier that represents a particular type of warning message. The available \texttt{warnclasses} are:

- \texttt{ALN} Segment alignment
- \texttt{BRK} Brackets needed
- \texttt{GTP} Global type doesn’t match symbol type
- \texttt{ICG} Inefficient code generation
- \texttt{INT} INT 3 generation
- \texttt{LCO} Location counter overflow
- \texttt{MCP} MASM compatibility pass
- \texttt{OPI} Open IF conditional
- \texttt{OPP} Open procedure
- \texttt{OPS} Open segment
- \texttt{OVF} Arithmetic overflow
- \texttt{PDC} Pass-dependent construction
- \texttt{PRO} Write-to-memory in protected mode using CS
- \texttt{PQK} Assuming constant for [const] warning
- \texttt{RES} Reserved word warning
- \texttt{TPI} illegal warning

\textbf{Note} \texttt{WARN} without a \texttt{warnclass} enables all warnings. \texttt{WARN} followed by an identifier only enables that particular warning.

Notice that the identifiers used by \texttt{WARN} are the same as those used by the /W command-line option.

Here’s an example using \texttt{WARN}:

\begin{verbatim}
WARN OVF ;enables arithmetic overflow warning
DW 1000h * 1234h ;overflow warning will occur
\end{verbatim}
Use the NOWARN directive to disable specific (or all) warning messages. NOWARN uses the same identifiers described earlier under WARN. Here’s an example that uses NOWARN:

```
NOWARN OVF ;disable arithmetic overflow warnings
DW 1000h * 1234h ;doesn't warn now
```

**Note** NOWARN without a warnclass disables all warnings. NOWARN with an identifier disables only that particular warning.

## Multiple error-message reporting

By default, Turbo Assembler only allows one error message to be reported for each line of source code. If a source line contains multiple errors, Turbo Assembler reports the most-significant error first. You can control the number of error messages you get for each source line by using the MULTERRS and NOMULTERRS directives.

The MULTERRS directive allows the assembler to report more than one error message for each source line. This is sometimes helpful in locating the cause of a subtle error or when the source line contains more than one error.

Note that sometimes additional error messages can be a “chain reaction” caused by the first error condition; these “chain” error messages may disappear once you correct the first error.

Here’s an example of the MULTERRS directive:

```
MULTERRS
mov ax,[bp+abc] ;produces two errors:
;1) Undefined symbol: abc
;2) Need right square bracket
```

**Note** The NOMULTERRS directive only lets one error or warning message (the most significant message) appear for each source line. When you correct this error, the other error messages may disappear as well. To avoid this problem, use the MULTERRS directive to see all of the error messages.

Here is an example of using the NOMULTERRS directive:

```
NOMULTERRS
mov ax,[bp+abc] ;one error:
;1) Undefined symbol: abc
```
Creating object-oriented programs

Object-oriented programming is an approach to software design that is based on objects rather than procedures. This approach maximizes modularity and information hiding. The underlying premise behind object-oriented programming is the binding or encapsulation of a data structure with procedures for manipulating the data in the structure into a unit.

Object-oriented design provides many advantages. For example, every object encapsulates its data structure with the procedures used to manipulate instances of the data structure. This removes interdependencies in code that can quickly make maintenance difficult. Objects can also inherit a data structure and other characteristics from a parent object, which saves work and lets you transparently use a single chunk of code for many purposes.

If you’re not an experienced Turbo Assembler user, you might want to skim through this chapter now, but come back to it later after reading the other chapters of this manual. We’ve put it here to make you aware of these features, but object-oriented programming in Turbo Assembler is really an advanced topic. It will make more sense after going through the rest of the manual.

Terminology

Assembler, C++, and Pascal use different terms for various entities in object-oriented programming. The following table outlines the differences among these languages.

<table>
<thead>
<tr>
<th>Turbo Assembler</th>
<th>Borland C++</th>
<th>Borland Pascal</th>
</tr>
</thead>
<tbody>
<tr>
<td>method</td>
<td>method</td>
<td>method</td>
</tr>
<tr>
<td>method procedure</td>
<td>member function</td>
<td></td>
</tr>
<tr>
<td>object</td>
<td>class</td>
<td>object</td>
</tr>
<tr>
<td>base object</td>
<td>base class</td>
<td>base object</td>
</tr>
</tbody>
</table>
Why use objects in Turbo Assembler?

Most people think of assembly language as a low-level language. Turbo Assembler, however, provides many of the features of a high-level language (such as abstract data types, and easy interfacing to other languages). The addition of object-oriented data structures gives Turbo Assembler the power to create object-oriented programs as easily as high-level languages while retaining the speed and flexibility of assembly language.

What is an object?

An object consists of a data structure and associated procedures (called methods) that manage data stored in instances of the data structure.

An object can inherit characteristics from a parent object. This means that the new object's data structure includes the parent object's data structure, as well as any new data. Also, the new object can call all the method procedures of the parent object, as well as any new method procedures it declares.

Note

We strongly recommend that you use Ideal mode for object-oriented programming in Turbo Assembler because symbol scoping is global in MASM, which means you can't distinguish the different positions of shown methods.

An object having no inheritance is called a base object; an object that inherits another is a derived object.

Turbo Assembler defines several symbols you can use when declaring objects. The following table lists these symbols.

Table 4.2 Symbols defined for objects

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>@Object</td>
<td>A text macro containing the name of the current object (the object last declared).</td>
</tr>
<tr>
<td>&lt;objectname&gt;</td>
<td>A STRUC data type that describes the object's data structure.</td>
</tr>
<tr>
<td>@Table_&lt;objectname&gt;</td>
<td>A TABLE data type containing the object's method table, which is not the same as an instance of the virtual method table.</td>
</tr>
<tr>
<td>@TableAddr_&lt;objectname&gt;</td>
<td>A label describing the address of the instance of the object's virtual method table, if there is one.</td>
</tr>
</tbody>
</table>
A sample object

As an example of where you can use objects, consider any program that uses linked lists. Think of a linked list as an object consisting of the linked list data and the operations (methods) that you can perform on it.

The linked list data consists of pointers to the head and tail of the linked list (this example contains a doubly linked list because of its flexibility). Each element of the linked list is a separate object instance.

The following operations provide the power needed to use a linked list:

- Creating the linked list (allocating memory for it).
- Destroying the linked list (deallocating memory for it).
- Initializing the linked list.
- Deinitializing the linked list.
- Inserting an item into the middle of the linked list before an existing item.
- Appending an item to the end of the linked list.
- Deleting an item from the linked list.
- Returning the first item in the linked list.
- Returning the last item in the linked list.

Keep in mind that create and initialize, as well as destroy and deinitialize methods are not synonymous. create and destroy methods allocate and deallocate memory for the linked list object, while the initialize and deinitialize methods only initialize and deinitialize previously allocated instances of the object. If you don’t combine initialization with creation, it’s possible to statically allocate linked list objects.

You can see how the linked list object can be inherited by a queue or stack object, since a queue or a stack can be implemented as a linked list with limited operations. For example, you can implement a queue as a linked list where items can be added to the start and taken off the end. If you implement a queue in this way, you must disable the inherited linked list methods that are illegal on a queue (such as inserting into the middle of the list).

Declaring objects

Declaring an object consists of declaring the data structure for the object, and declaring the method procedures that you can call for the object. Declaring an object does not involve creating an instance of the object. You’ll learn how to do this later.

Declaring a base object

When you declare an object, Turbo Assembler creates a STRUC that declares the data for the object, and a TABLE that declares the methods for the object. The object’s data declaration is a structure with the same name as the object. The object’s method declarations are stored in a TABLE data type, named @Table_<objectname>.
For example, for the list object, two data types are declared:

```
list
    A STRUC declaring the following members:
    list_head    dword pointer to head of list
    list_tail    dword pointer to tail of list

@Table_list
    A TABLE declaring the following methods:
    construct    dword pointer to the procedure list_construct
    destroy      dword pointer to the procedure list_destroy
    and so on...
```

STRUC declares the data for the object that is created whenever you create an instance of the object. TABLE declares the table of default method procedures for the declaration. Turbo Assembler maintains this data type; it does not create an instance of the table anywhere in your program memory. However, you'll see later that you must include an instance of the table for any object that uses virtual methods.

Here's an example of an object declaration for a linked list (for more on STRUC as it applies to declaring objects, see Chapter 8):

```
list STRUC GLOBAL METHOD {
    construct:dword = list_construct ;list constructor procedure
    destroy:dword = list_destroy      ;list destructor procedure
    init:dword = list_init            ;list initializer procedure
    deinit:dword = list_deinit         ;list deinitializer procedure
    virtual insert:word = list_insert ;list node insert procedure
    virtual append:word = list_append ;list node append procedure
    virtual remove:word = list_delete ;list node remove procedure
    virtual first:word = list_first   ;list first node procedure
    virtual last:word = list_last     ;list last node procedure
}

list_head dd? ;list head pointer.
list_tail dd? ;list tail pointer
ENDS
```

In this example, the METHOD keyword shows that you're using an extended form of STRUC, and are defining an object called list.

Each entry consists of a method name, a colon, and the size of a pointer to the method procedure (WORD for near procedures, DWORD for far procedures). This is followed by an equal sign, and the name of the procedure to call for that method.

Let's look at this example to see what's happening.

METHOD indicates an object method call and is followed by a list of the method procedure declarations for the object. These declarations are enclosed in braces ({ }) because the list of methods requires more than one line.

Each method declaration tells Turbo Assembler which procedure it should use to manipulate the object when invoking that method name. For example, the first method procedure declaration

```
    construct:dword = list_construct
```
declares a method named *construct* that is a far procedure (because a DWORD stores the pointer to it). The actual procedure name of the method is *list_construct*, which should be defined elsewhere in the source code.

Turbo Assembler considers a method to be virtual if it’s preceded by the keyword **VIRTUAL**. When you call such a method, Turbo Assembler will locate the method’s procedure address by looking it up from a table present in memory at run time. Otherwise, the method is a static method, meaning that Turbo Assembler can determine its address at compile time. For example, the method *construct* is a static method, while the method *insert* is declared as a virtual method. Later in this chapter, we’ll explain why you might want to choose virtual or static methods.

The data structure for the method immediately follows the method procedure declaration section. This definition uses the syntax for the standard **STRUC** directive. This example contains declarations for the linked list’s head and tail pointers.

The method declaration portion of the object declaration doesn’t place any data in the object’s data structure unless you’ve used virtual methods. Instead, these declarations cause Turbo Assembler to build a separate table data structure that contains the specified method procedure addresses as default values. You should have an instance of this table for every object, and you must explicitly place the table. We’ll explain how to do this later in this chapter.

Since the object declaration must exist in the module containing the method procedures for the object (as well as included in any source code that uses the object), you should declare the object itself in a separate file that can be **INCLUDED** into the source code. We recommend using a file name in the form *objectname.ASO* (ASsembly Object). This file should consist of only the object declaration. The object methods should be in another source file so that you can include the object declaration wherever you need it. For example, the linked list object declaration in the previous example would be placed in the file *LIST.ASO*. The file *LIST.ASM* could be used to define the object’s method procedures. Any program making use of the objects would include LIST.ASO, but not LIST.ASM.

The keyword **GLOBAL** in the object declaration causes Turbo Assembler to publish information that lets you use the object in a module other than the one it’s defined in. The object declaration must also be included in all modules that use the object.

**Declaring a derived object**

An object that inherits another object’s methods and data is called a *derived* object. You can’t override the members of the parent data structure, but you can override the individual methods by respecifying them in the new object method list.

An object can inherit any other single object, whether that other object is a base or derived object itself. The inherited object is called the *parent* object. The derived object inherits the data and methods of the parent object, so you should only use inheritance when these methods and data are useful to the new object.

For example, you can define a queue object that inherits the linked list object because you can implement a queue as a linked list. Here’s an example of such a derived object:
queue STRUC GLOBAL list METHOD {
    init:DWORD=queue_init
    virtual insert:word = queue_insert  ;(queue node insert
  )
    virtual remove:word = queue_delete  ;(queue node delete
  )
    virtual first:word = queue_first   ;(queue first node procedure)
    virtual last:word = queue_last     ;(queue end node procedure)
    virtual enqueue:word = list_append ;queue enqueue procedure
    virtual dequeue:word = queue_dequeue ;queue dequeue procedure
}
ENDS

Placing the object name list before the METHOD keywords tells Turbo Assembler that the new object queue inherits the methods and data of the object, list. Any object name placed in this location will be inherited by the object being declared. You can use only one name (only single inheritance is supported).

The new queue object inherits all the data and methods from the list object, unless you override it. Note that queue needs its own init to install the pointer to the virtual method table for queues.

The inherited insert, remove, first, and last method declarations for the queue are respecified in the declaration, so these methods are replaced with the indicated procedures.

Two new methods have been declared for the queue: enqueue and dequeue. Notice that the method procedure for enqueue is the same as for appending to a linked list. However, we need a new procedure to dequeue from the queue, and this we call queue_dequeue.

The queue object has no additional data declared other than what it inherits from list. It inherits the linked list’s head and tail pointers, which are still needed for the queue because of the linked list methods used to manage the queue.

---

**Declaring a method procedure**

Method procedures manipulate instances of the object. They are much like library routines in that they should have a well-defined call and a return value interface, but knowledge of how the method procedures work internally is not necessary.

The method procedures for an object should provide comprehensive management of the objects; that is, they should be the only procedures allowed direct access to the objects. Furthermore, you should use the concepts of data abstraction when you design the methods: You should be able to call the method procedures without having any knowledge of the inner workings of the method procedures.

In all other respects, you can write method procedures for any language or interface you want, although usually C++ or Pascal calling conventions are used. Any arguments to the procedures are up to you as well. One argument that is usually required is a pointer to an object instance. Some method procedures might require additional parameters. For example, the initialization method for the list object requires just the pointer to the
list object, while the list insert method requires a pointer to the list, a pointer to the new node to insert, and a pointer to the node it's inserted after.

**Note** There are advantages and disadvantages to using both static and virtual methods. Static methods are resolved at compile time, and result in direct calls to the method procedure. This makes the call faster, and does not require you to use intermediate registers (as in virtual method calls). However, since these calls are resolved at compile time, static method calls don't have the flexibility of virtual method calls.

Virtual method calls are made indirectly through an instance of the virtual method table for the object. The fact that the call is indirect gives virtual methods the disadvantage of requiring you to use intermediate registers when you make the call (which could complicate your code). A big advantage, however, is that virtual method calls are resolved at run time. Thus, you can make virtual method calls for a derived object by calling a common ancestor object's method without having to know exactly what sort of descendant object you're dealing with.

**Note** Declare static and virtual method procedures exactly the same way as any other procedure, with the following exception: if you omit the procedure name for virtual methods, you'll cause an empty uninitialized location in the virtual method table and Turbo Assembler won't warn you if you do this. Omitting the procedure name is an error if the method is not virtual, since virtual methods don't go into the table.

Here's an example of a method procedure:

```pascal
list_construct PROC PASCAL FAR
USES ds
    ;-- Allocate the Linked-List object --
    ;;<<do the allocation here>>
    .ret
ENDP
```

The virtual method table

The virtual method table (VMT) is a table of addresses of the procedures that perform virtual methods. Usually this table is placed in the program’s data segment. Any object having virtual methods requires an instance of the VMT somewhere in the program.

Use the **TBLINST** directive to create the instance of the VMT for an object. Since this directive creates a table for the most recently declared object, you should place this directive immediately after the object declaration, as in the following:

```assembly
INCLUDE list.aso
DATASEG
TBLINST
```

Chapter 4, Creating object-oriented programs 49
Initializing the virtual method table

Simply creating the instance of the VMT is not enough to let you make calls to virtual methods. Every object with virtual methods includes a pointer to the VMT in its data structure. You must initialize this pointer whenever you create an instance of an object, and can use TBLINIT to do so.

Initialize the VMT pointer in the \textit{init} method for the object as follows:

\begin{verbatim}
;Initialize a Linked List object.
;This is the method "init".
;This must be a static method!
list_init PROC PASCAL FAR
ARG @@list:dword
USES ds,bx
lds bx,@@list
    ;-- Initialize any virtual method table for the object at ds:bx
TBLINIT ds:bx
    ;-- Initialize the object's data --
    ;;;<initialize any data for the object here...>>
ret
ENDP
\end{verbatim}

Notice that the \textit{init} method must be static because you can't call a virtual method for an object instance until after you initialize the virtual table pointer.

Calling an object method

Use the CALL instruction to invoke object methods. Turbo Assembler provides an extension to the standard CALL instruction, CALL..METHOD, for calling method procedures.

Notice that the syntax for CALL is similar for calling both static or virtual methods.

Calling a static method

When making a call to a method procedure, you should write the CALL..METHOD instruction as if you were making a call to a virtual method, even if you know that you’re calling a static method. Doing so will have no ill effects on static method calls, and gives you the flexibility of changing methods from static to virtual or back again without having to change all the calls to the method. For the same reasons, you should specify a reasonable selection for the intermediate calling registers, even if you know that the method you’re calling is static.

Calls to static methods are resolved at compile time to direct calls to the desired method procedure for the object. However, when making the call, you should not make a direct call to the method procedure; instead, use the extended CALL..METHOD instruction.

The following example shows a sample call to the static \textit{init} method for the linked list object.
The call address itself is the address of an instance of the object. This address is used for syntactic reasons only; the actual call generated is a direct call to the method procedure.

In this example, the first call is to the `init` method for the object `list`. Since this is a static method, you make a direct call to the method procedure `list_init`. Turbo Assembler ignores the object instance, `foolist` (except that it's passed as an argument to the method procedure).

The method name is followed by the usual extended call language and parameter list. The language and parameters depend on the method you're calling, and one of the parameters is generally a pointer to the instance of the object. In this example, the method accepts a single parameter, which is a pointer to the instance of the object.

### Calling a virtual method

Any call to a virtual method requires an indirect call to the method procedure. You can use the extended `CALL..METHOD` instruction to let this happen. Turbo Assembler generates the following instructions to perform the call:

1. Load intermediate registers from the object instance with a pointer to the VMT.
2. Make an indirect call to the appropriate method.

Therefore, when you specify

```
CALL <instance> METHOD <object>:<method> USES <seg>:<reg> <calling_stuff>
```

the generated instructions are as follows:

```
MOV <reg>, [<instance>.<virtual_method_table_pointer>]
CALL [[<seg>:<reg>].<method>] <calling_stuff>
```

The first instruction loads the selected register `<reg>` with the address of the table from the VMT pointer field of the object structure. The second instruction makes an indirect call to the appropriate method in the table.

For example, a call of the form

```
CALL es:di method list:insert uses ds:bx pascal,es di,es dx,es cx
```

generates a sequence like

```
mov bx,[es:di.@Mptr_list]
CALL [ds:bx.insert] pascal, \
es di,es dx,es cx
```

Note that for objects declared with NEAR tables, only the offset register will be loaded by the `CALL..METHOD` instruction. The segment register should already contain the correct value. The following example shows how to make sure that the segment register is properly set up.

```
;Append a node at the end of a Linked-List object.
;This is the virtual method *list|append*.
list_append PROC PASCAL NEAR
```
ARG @@list: dword, \
@@new: dword
USES ds, bx, es, di
    mov ax, @@Data
    mov ds, ax
    les di, @@list
    sub ax, ax
    CALL es: di method list: insert uses ds: bx pascal,
    es di, @@new, ax ax
    ret
ENDP

Note  You can't call any virtual methods until after you initialize the VMT pointer in the
object’s data. This is because the pointer loads the address of the VMT (from which
the address of the desired virtual method procedure is retrieved). Thus, if you haven’t
initialized the pointer to the VMT, any virtual method call will result in a call to some
random address.

As another example, consider the base object node, which you can include in any object
placed in a linked list or a queue.

node STRUC GLOBAL METHOD {
    construct: dword = node_construct ; node constructor routine
    destroy: dword = node_destroy ; node destructor routine
    init: dword = node_init ; node initialization routine
    deinit: dword = node_deinit ; node deinitialization routine
    virtual next: word = node_adv ; next node routine
    virtual prev: word = node_back ; previous node routine
    virtual print: word = node_print ; print contents of node
}

node_next dd ? ; next node pointer
node_prev dd ? ; prev node pointer
ends

You can define any number of other objects inheriting the node object, to let it use a
linked list or queue. Here are two examples:

mlabel STRUC GLOBAL node METHOD {
    virtual print: word = label_print
}

label_name  db 80 dup (?)
label_addr db 80*2 dup (?)
label_city db 80 dup (?)
label_state db 2 dup (?)
label_zip db 10 dup (?)
ENDS

book STRUC GLOBAL node METHOD {
    virtual print: word = book_print
}

book_title db 80 dup (?)
book_author db 80 dup (?)
ENDS

52 Turbo Assembler User’s Guide
In the next example, we’re making calls to methods by calling `printit` for both label and book objects. It doesn’t matter what object gets passed to `printit`, as long as `node` is an ancestor. Because the print method is a virtual method, the call is made indirectly through the VMT for the object. For the first call to `printit`, the method procedure `label_print` is called, because we’re passing an instance of a label object. For the second call to `printit`, the method procedure `book_print` is called, because we’re passing an instance of a book object. Note that if the method `print` were static, then the call in `printit` would always call the `node_print` procedure (which is not desirable).

```pascal
  call printit pascal, «instance address of label object»
  call printit pascal, «instance address of book object»

  printit proc pascal near
  arg @@obj:dword
  uses ds,si,es,bx
  mov ax,@data
  mov es,ax
  lds si,@obj
  call ds:si method node.print uses es:bx pascal,ds si
  ret
  endp
```

**Calling ancestor virtual methods**

Using ancestor virtual methods can help you write methods for derived classes since you can reuse some of the code. For example, queues can use the same listing method as a list, as long as you specify whether the item is a queue or a list. Within the list class, you can have

```pascal
  virtual show:word = list_show
```

and within the queue class,

```pascal
  virtual show:word = queue_show
```

The `list_show` routine might print `LIST SHOW:`, followed by a listing of the individual items in the list. However, if the derived class `queue_show` uses the listing routine, it should print its own title, `QUEUE SHOW:`, and use `list_show` only for the mechanics of sequentially going through the list and printing individual elements. `list_show` can determine the kind of structure passed to it, and whether it should print the list title. If the routine for `list_show` looks at the pointer to the virtual method table (VMT) of the structure passed to it, it can determine whether the pointer matches the one installed for lists in the `list_init` routine (or if it differs). If the VMT pointer in the structure does not point to the VMT for lists, the structure is probably a derived type. `list_show` can do this checking with the following statements:

```pascal
  cmp [[[es:di]].@mptr_list],offset @TableAddr_LIST
  jne @@not a list ; Skip over printing the list title
```
If we come here, it is a list, and the list title should be printed.

@@not a list:
; Now show the individual list elements.

So how do we call the list class show method from within a queue_show routine? If you were to directly call list_show, you could have a problem if the name of the routine used for the show method of the list class ever changes. (You might not remember to change what queue_show calls.) If you put the following statement in queue_show,

```plaintext
call (es:di) method list:show
```

you’d have an infinite loop because even though list is specified as the class for which show should be called, the VMT will be used because show is a virtual method. Since the VMT for the structure would have been pointing to queue_show, you’d end up back in the same routine.

The best way to call the list class show method would be

```plaintext
call +@table_list | show
```

Turbo Assembler automatically translates this statement to a direct call to list_show, since list_show was specified as the value for the show element of the @table_list when the list class was declared. Note that even though list declares show to be virtual, specifying the call causes Turbo Assembler to make a direct call without the VMT lookup.

**Note** Virtual routines are usually called through an indirect lookup to a VMT.

In the event that you need to use the VMT for the list class (for example, some initialization routine might change the show element of the table to point to different routines depending on what output device to use for the show command of all list class elements), the following statements use the list class VMT:

```plaintext
mov bx, offset @TABLEADDR_LIST
call [@table_list ptr es:bx].SHOW
```

This is very similar to the sequence of instructions that Turbo Assembler uses to make the indirect call using the VMT.

**More on calling methods**

Often, you might find it necessary to call a parent object’s method from inside a derived method procedure. You can also use the CALL..METHOD statement to do this.

You can use the JMP instruction with the METHOD extension in the same way you use the CALL..METHOD instruction. This instruction provides optimal tail recursion. See Chapter 12 for more information about the CALL..METHOD and JMP..METHOD instructions.
Creating an instance of an object

To create an instance of an object, you can call an object’s constructor method (which allocates memory for an object instance) or allocate an instance of the object in a predefined (static) data segment.

You can create an instance of the object exactly the same way you create an instance of a structure. For example, examine the following instances of objects:

```plaintext
foolist list {} ;instance of a list
fooqueue label queue
  queue {} ;instance of a queue
  queue {list_head=mynode, list_tail=mynode} ;instance of a queue
```

When you create an instance of an object, you can override any of the object’s default data values as defined in the object declaration by specifying the overriding values inside the braces. You can’t, however, override the methods for an object when you create an instance of an object.

Programming form for objects

It’s a good idea to keep method procedures in a separate file from the method declaration, and from the code that uses the object. We recommend placing method procedures in a file with the name of the object and an extension of .ASM. For example, the method procedures for the linked-list object would go into the file LIST.ASM. The method procedure file must INCLUDE the method declaration from the .ASO file.

An example of the method procedures for the list object is described at the end of this chapter. This excerpt from the LIST.ASM file (on the example disks) shows the general structure of this file.

```plaintext
;-------------------------------
;-- Define Linked-List objects --
;-------------------------------

MODEL SMALL
LOCALS

;** Define Linked-List object **
INCLUDE node.aso

;** Create instance of Linked-List virtual method table **
DATASEG
TBLINST

;** Linked-List methods **
CODESEG
;;<<include all method procedures here>>
```
In general, you should use the following form for object-oriented programming in Turbo Assembler:

<table>
<thead>
<tr>
<th>File</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;object&gt;.ASO</td>
<td>INCLUDEs &lt;parent_object&gt;.ASO, if any; contains GLOBAL object declaration and a GLOBAL directive for each method procedure.</td>
</tr>
<tr>
<td>&lt;object&gt;.ASM</td>
<td>INCLUDEs &lt;object&gt;.ASO; contains TBLINST directive and method procedure declarations; has an init method with a TBLINIT somewhere inside.</td>
</tr>
</tbody>
</table>

Note that you can use the TBLINST and TBLINIT directives even when there are currently no virtual methods in the object; in that case, no action is taken.

We therefore recommend using the TBLINST and TBLINIT directives regardless of whether virtual methods are currently present in an object: Place the TBLINST directive in an appropriate data segment and the TBLINIT directive in the object’s initialization method (which must be a static method). You must call this method before using any other methods for the object.
Expressions and symbols are fundamental components of an assembly language program. Use expressions to calculate values and memory addresses. Symbols represent different kinds of values. This chapter describes the different types of these language components, and how you can use them.

**Constants**

Constants are numbers or strings that Turbo Assembler interprets as a fixed numeric value. You can use a variety of different numeric formats, including decimal, hexadecimal, binary, and octal.

**Numeric constants**

A numeric constant in Turbo Assembler always starts with a digit (0–9), and consists of an arbitrary number of alphanumerical characters. The actual value of the constant depends on the radix you select to interpret it. Radixes available in Turbo Assembler are binary, octal, decimal, and hexadecimal, as shown in Table 5.1:

<table>
<thead>
<tr>
<th>Table 5.1 Radixes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Radix</strong></td>
</tr>
<tr>
<td>Binary</td>
</tr>
<tr>
<td>Octal</td>
</tr>
<tr>
<td>Decimal</td>
</tr>
<tr>
<td>Hexadecimal</td>
</tr>
</tbody>
</table>

Note that for hexadecimal constants, you can use both upper- and lowercase letters.
Turbo Assembler determines the radix of a numeric constant by first checking the LAST character of the constant. The characters in the following table determine the radix used to interpret the numeric constant.

### Table 5.2  Characters determining radices

<table>
<thead>
<tr>
<th>Character</th>
<th>Radix</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Binary</td>
</tr>
<tr>
<td>O</td>
<td>Octal</td>
</tr>
<tr>
<td>Q</td>
<td>Octal</td>
</tr>
<tr>
<td>D</td>
<td>Decimal</td>
</tr>
<tr>
<td>H</td>
<td>Hexadecimal</td>
</tr>
</tbody>
</table>

You can use both uppercase and lowercase characters to specify the radix of a number. If the last character of the numeric constant is not one of these values, Turbo Assembler will use the current default radix to interpret the constant. The following table lists the available numeric constants and their values.

### Table 5.3  Numeric constants

<table>
<thead>
<tr>
<th>Numeric constant</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>77d</td>
<td>77 decimal</td>
</tr>
<tr>
<td>77h</td>
<td>77 hexadecimal</td>
</tr>
<tr>
<td>ffffh</td>
<td>Illegal; doesn't start with a digit</td>
</tr>
<tr>
<td>0ffffh</td>
<td>FFFF hexadecimal</td>
</tr>
<tr>
<td>88</td>
<td>Interpretation depends on current default radix</td>
</tr>
</tbody>
</table>

### Changing the default radix

You can use the **RADIX** or **.RADIX** directives to change the current default radix. Use the following syntax for Ideal mode:

```
RADIX expression
```

Here's the MASM mode syntax:

```
.RADIX expression
```

*expression* must have a value of either 2 (binary), 8 (octal), 10 (decimal), or 16 (hexadecimal). Turbo Assembler assumes that the current default radix is decimal while it processes the **RADIX** directive.

### String constants

String constants always begin with a single or double quote, and end with a matching single or double quote. Turbo Assembler converts the characters between the quotes to ASCII values.

Sometimes, you might want to include a quote within a string constant. To do this, use a pair of matching quotes as a single matching quote character within the string. For example,
Symbols

A symbol represents a value, which can be a variable, address label, or an operand to an assembly instruction and directive.

Symbol names

Symbol names are combinations of letters (both uppercase and lowercase), digits, and special characters. Symbol names can't start with a digit. Turbo Assembler treats symbols as either case sensitive or case insensitive. The command line switches /ML, /MU, and /MX control the case sensitivity of symbols. For more information about these command-line switches, see Chapter 2.

Symbols names can be up to 255 characters in length. By default, symbol names are significant up to 32 characters. You can use the /MV command-line switch to change the number of characters of significance in symbols.

The underscore (_), question mark (?), dollar sign ($), and at-sign (@) can all be used as part of a symbol name. In MASM mode only, you can use a dot (.) as the first character of a symbol name. However, since it's easy to confuse a dot at the start of a symbol with the dot operator (which performs a structure member operation), it's better not to use it in symbol names.

Symbol types

Each symbol has a type that describes the characteristics and information associated with it. The way you define a symbol determines its type. For example, you can declare a symbol to represent a numeric expression, a text string, a procedure name, or a data variable. Table 5.4 lists the types of symbols that Turbo Assembler supports.

<table>
<thead>
<tr>
<th>Symbol type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>An address. Data subtypes are UNKNOWN, BYTE, WORD, DWORD, PWord or FWord, QWord, TBYTE, and an address of a named structure or table. Code subtypes are SHORT, NEAR, and FAR</td>
</tr>
<tr>
<td>text_macro</td>
<td>A text string</td>
</tr>
<tr>
<td>alias</td>
<td>An equivalent symbol</td>
</tr>
<tr>
<td>numerical_expr</td>
<td>The value of a numerical expression</td>
</tr>
<tr>
<td>multiline_macro</td>
<td>Multiple text lines with dummy arguments</td>
</tr>
<tr>
<td>struc/union</td>
<td>A structure or union data type</td>
</tr>
<tr>
<td>table</td>
<td>A table data type</td>
</tr>
<tr>
<td>struc/table_member</td>
<td>A structure or table member</td>
</tr>
<tr>
<td>record</td>
<td>A record data type</td>
</tr>
<tr>
<td>record_field</td>
<td>A record field</td>
</tr>
<tr>
<td>enum</td>
<td>An enumerated data type</td>
</tr>
</tbody>
</table>
Table 5.4  Symbol types (continued)

<table>
<thead>
<tr>
<th>Symbol type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>segment</td>
<td>A segment</td>
</tr>
<tr>
<td>group</td>
<td>A group</td>
</tr>
<tr>
<td>type</td>
<td>A named type</td>
</tr>
<tr>
<td>proctype</td>
<td>A procedure description type</td>
</tr>
</tbody>
</table>

**Simple address subtypes**

Symbols subtypes describe whether the symbol represents the address of a byte, a word, and so forth. Table 5.5 shows the simple address subtypes that Turbo Assembler provides.

Table 5.5  Address subtypes

<table>
<thead>
<tr>
<th>Type expression</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNKNOWN</td>
<td>Unknown or undetermined address subtype.</td>
</tr>
<tr>
<td>BYTE</td>
<td>Address describes a byte.</td>
</tr>
<tr>
<td>WORD</td>
<td>Address describes a word.</td>
</tr>
<tr>
<td>DWORD</td>
<td>Address describes a 4-byte quantity.</td>
</tr>
<tr>
<td>PWORD or FWORD</td>
<td>Address describes a 6-byte quantity.</td>
</tr>
<tr>
<td>QWORD</td>
<td>Address describes an 8-byte quantity.</td>
</tr>
<tr>
<td>TBYTE</td>
<td>Address describes a 10-byte quantity.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Address describes a short label/procedure address.</td>
</tr>
<tr>
<td>NEAR</td>
<td>Address describes a near label/procedure address.</td>
</tr>
<tr>
<td>FAR</td>
<td>Address describes a far label/procedure address.</td>
</tr>
<tr>
<td>PROC</td>
<td>Address describes either a near or far label/procedure address, depending on the currently selected programming model.</td>
</tr>
<tr>
<td>DATAPTR</td>
<td>Address describes either a word, dword, or pword quantity, depending on the currently selected programming model.</td>
</tr>
<tr>
<td>CODEPTR</td>
<td>Address describes either a word, dword, or pword quantity, depending on the currently selected programming model.</td>
</tr>
<tr>
<td>struc/union_name</td>
<td>Address describes an instance of the named structure or union.</td>
</tr>
<tr>
<td>table_name</td>
<td>Address describes an instance of the named table.</td>
</tr>
<tr>
<td>record_name</td>
<td>Address describes an instance of the named record; either a byte, word, or dword quantity.</td>
</tr>
<tr>
<td>enum_name</td>
<td>Address describes an instance of the named enumerated data type; either a byte, word, or dword quantity.</td>
</tr>
<tr>
<td>type_name</td>
<td>Address describes an instance of the named type.</td>
</tr>
<tr>
<td>TYPE expression</td>
<td>Address describes an item whose subtype is the address subtype of the expression; Ideal mode only.</td>
</tr>
<tr>
<td>proctype_name</td>
<td>Address describes procedure of proctype.</td>
</tr>
</tbody>
</table>
Describing a complex address subtype

Several directives let you declare and use complex address subtypes. These type expressions are similar to C in that they can represent multiple levels of pointer indirection, for example, the complex type expression

\[ 	ext{PTR} \ \text{WORD} \]

represents a pointer to a word. (The size of the pointer depends on the segmentation model you selected with \texttt{MODEL}.)

Table 5.6 shows a syntax summary of complex address subtypes:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>simple_address_subtype</td>
<td>the specified address subtype</td>
</tr>
<tr>
<td>[dist]PTR[complex_address_subtype]</td>
<td>a pointer to the specified complex address subtype, the size of which is determined by the current \texttt{MODEL} or by the specified distance, if present</td>
</tr>
</tbody>
</table>

You can describe the optional distance parameter in the following ways:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEAR</td>
<td>use a near pointer; can be either 16 or 32 bits, depending on the current model</td>
</tr>
<tr>
<td>FAR</td>
<td>use a far pointer; can be either 32 or 48 bits, depending on current model</td>
</tr>
<tr>
<td>SMALL NEAR</td>
<td>use a 16-bit pointer; 80386 and 80486 only</td>
</tr>
<tr>
<td>LARGE NEAR</td>
<td>use a 32-bit near pointer; 80386 and 80486 only</td>
</tr>
<tr>
<td>SMALL FAR</td>
<td>use a 32-bit far pointer; 80386 and 80486 only</td>
</tr>
<tr>
<td>LARGE FAR</td>
<td>use a 48-bit far pointer; 80386 and 80486 only</td>
</tr>
</tbody>
</table>

The type of the object being pointed to is not strictly required in complex pointer types; Turbo Assembler only needs to know the size of the type. Therefore, forward references are permitted in complex pointer types (but not in simple types).

Expressions

Using expressions lets you produce modular code, because you can represent program values symbolically. Turbo Assembler performs any recalculation required because of changes (rather than requiring you to do them).

Turbo Assembler uses standard infix notation for equations. Expressions can contain operands and unary or binary operators. Unary operators are placed before a single
operand; binary operators are placed between two operands. Table 5.8 shows examples of simple expressions.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Evaluates to</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>constant 5</td>
</tr>
<tr>
<td>-5</td>
<td>constant -5</td>
</tr>
<tr>
<td>4+3</td>
<td>constant 7</td>
</tr>
<tr>
<td>4*3</td>
<td>constant 12</td>
</tr>
<tr>
<td>4<em>3+2</em>1</td>
<td>constant 14</td>
</tr>
<tr>
<td>4*(3+2)*1</td>
<td>constant 21</td>
</tr>
</tbody>
</table>

Appendix B contains the full Backus-Naur form (BNF) grammar that Turbo Assembler uses for expression parsing in both MASM and Ideal modes. This grammar inherently describes the valid syntax of Turbo Assembler expressions, as well as operator precedence.

**Expression precision**

Turbo Assembler always uses 32-bit arithmetic in Ideal mode. In MASM mode, Turbo Assembler uses either 16- or 32-bit arithmetic, depending on whether you select the 80386 processor. Therefore, some expressions might produce different results depending on which processor you’ve selected. For example,

(1000h 1000h) / 1000h

evaluates to 1000h if you select the 80386 processor, or to 0 if you select the 8086, 80186, or 80286 processors.

**Constants in expressions**

You can use constants as operands in any expression. For example,

```assembly
mov ax,5
```

"5" is a constant operand

**Symbols in expressions**

When you use a symbol in an expression, the returned value depends on the type of symbol. You can use a symbol by itself or in conjunction with certain unary operators that are designed to extract other information from the entity represented by the symbol.

**Registers**

Register names represent 8086-family processor registers, and are set aside as part of the expression value. For example,

5+ax+7
This expression has a final value of \( ax + 12 \), because \( AX \) is a register symbol that Turbo Assembler sets aside. The following list contains register symbols:

- **8086**: AX, BX, CX, DX, SI, DI, BP, CS, DS, ES, SS
- **80186, 80286**: Same as 8086
- **80386**: 8086 registers, plus EAX, EBX, ECX, EDX, ESI, EDI, EBP, FS, GS, CR0, CR2, CR3, DR0, DR1, DR2, DR3, DR6, DR7
- **80486**: 80386 registers, plus: TR3, TR4, TR5

### Standard symbol values

Some symbols always represent specific values and don't have to be defined for you to use them. The following table lists these symbols and their values.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>Current program counter</td>
</tr>
<tr>
<td>NOTHING</td>
<td>0</td>
</tr>
<tr>
<td>?</td>
<td>0</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>0</td>
</tr>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>WORD</td>
<td>2</td>
</tr>
<tr>
<td>DWORD</td>
<td>4</td>
</tr>
<tr>
<td>PWORD</td>
<td>6</td>
</tr>
<tr>
<td>FWORD</td>
<td>6</td>
</tr>
<tr>
<td>QWORD</td>
<td>8</td>
</tr>
<tr>
<td>TBYTE</td>
<td>10</td>
</tr>
<tr>
<td>NEAR</td>
<td>Offffh</td>
</tr>
<tr>
<td>FAR</td>
<td>Offfeh</td>
</tr>
<tr>
<td>PROC</td>
<td>Either Offffh or Offfeh, depending on current model</td>
</tr>
<tr>
<td>CODEPTR</td>
<td>Either 2 or 4, depending on current model</td>
</tr>
<tr>
<td>DATAPTR</td>
<td>Either 2 or 4, depending on current model</td>
</tr>
</tbody>
</table>

### Simple symbol values

Turbo Assembler returns the following values for symbols used by themselves:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>address_name</td>
<td>Returns the address.</td>
</tr>
<tr>
<td>numerical_expr_name</td>
<td>Returns the value of the numerical expression.</td>
</tr>
<tr>
<td>table_name 1 table_member_name</td>
<td>Returns the default value for the table member specified in the definition of the table.</td>
</tr>
<tr>
<td>struc/table_member_name</td>
<td>Returns the offset of the member within the table or structure (MASM mode only).</td>
</tr>
</tbody>
</table>
Table 5.10  Values of symbols used by themselves (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_name</td>
<td>Returns a mask where the bits reserved to represent bit fields in the record definition are 1, the rest are 0.</td>
</tr>
<tr>
<td>record_name &lt;...&gt;</td>
<td>Returns the initial value a record instance would have if it were declared with the same text enclosed in angle brackets (see Chapter 12 for details).</td>
</tr>
<tr>
<td>record_field_name</td>
<td>Similar to record_name &lt;...&gt;.</td>
</tr>
<tr>
<td>enum_name</td>
<td>Returns a mask where the bits required to represent the maximum value present in the enum definition are 1, the rest are 0.</td>
</tr>
<tr>
<td>segment_name</td>
<td>Returns the segment value.</td>
</tr>
<tr>
<td>group_name</td>
<td>Returns the group value.</td>
</tr>
<tr>
<td>struc/union_name</td>
<td>Returns the size in bytes of the structure or union, but only if it is 1, 2, or 4; all other sizes return a value of 0.</td>
</tr>
<tr>
<td>type_name</td>
<td>If the type is defined as a synonym for a structure or union, the value returned is the same as for a structure or union. Otherwise, the size of the type is returned (with 0FFFF for short and near labels, and 0FFFFFF for far labels).</td>
</tr>
<tr>
<td>proctype_name</td>
<td>Returns 0FFFFFFh if the proctype describes a near procedure, or 0FFFFEh for a far procedure.</td>
</tr>
</tbody>
</table>

All other symbols types return the value 0.

Note that when you use a text macro name in an expression, Turbo Assembler substitutes the string value of the text macro for the text macro symbol. Similarly, when you use an alias name, Turbo Assembler substitutes the symbol value that the alias represents for the alias symbol.

The LENGTH unary operator

The LENGTH operator returns information about the count or number of entities represented by a symbol. The actual value returned depends on the type of the symbol, as shown in the following table.

Table 5.11  LENGTH operator return values

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LENGTH address_name</td>
<td>Returns the count of items allocated when the address name was defined.</td>
</tr>
<tr>
<td>LENGTH struc/table_member_name</td>
<td>Returns the count of items allocated when the member was defined (MASM mode only).</td>
</tr>
</tbody>
</table>

The length operator (when applied to all other symbol types) returns the value 1. Here are some examples using the LENGTH operator:

```assembly
MSG   DB "Hello"
array DW 10 DUP (4 DUP (1),0)
numsrs DD 1,2,3,4
lmsg = LENGTH msg                  ;=1, no DUP
larray = LENGTH array              ;=10, DUP repeat count
lnumsrs = LENGTH numsrs            ;=1, no DUP
```
The **SIZE unary operator**

The **SIZE** operator returns size information about the allocated data item. The value returned depends on the type of the symbol you’ve specified. The following table lists the available values for **SIZE**.

**Table 5.12 ** SIZE values

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIZE address_name</td>
<td>In Ideal mode, returns the actual number of bytes allocated to the data variable. In MASM mode, returns the size of the subtype of address_name (UNKNOWN=0, BYTE=1, WORD=2, DWORD=4, PWORD=DWORD=6, QWORD=8, TBYTE=10, SHORT=NEAR=OFFFFH, FAR=OFFFEH, structure address=size of structure) multiplied by the value of LENGTH address_name. See also <strong>WIDTH</strong>.</td>
</tr>
<tr>
<td>SIZE struc/union_name</td>
<td>Returns the number of bytes required to represent the structure or union.</td>
</tr>
<tr>
<td>SIZE table_name</td>
<td>Returns the number of bytes required to represent the table.</td>
</tr>
<tr>
<td>SIZE struc/table_member_name</td>
<td>Returns the quantity TYPE struc/table_member_name * LENGTH struc/table_member_name (MASM mode only).</td>
</tr>
<tr>
<td>SIZE record_name</td>
<td>Returns the number of bytes required to represent the total number of bits reserved in the record definition; either 1, 2, or 4.</td>
</tr>
<tr>
<td>SIZE enum_name</td>
<td>Returns the number of bytes required to represent the maximum value present in the enum definition; either 1, 2, or 4.</td>
</tr>
<tr>
<td>SIZE segment_name</td>
<td>Returns the size of the segment in bytes.</td>
</tr>
<tr>
<td>SIZE type_name</td>
<td>Returns the number of bytes required to represent the named type, with short and near labels returning OFFFFH, and far labels returning OFFFEH.</td>
</tr>
</tbody>
</table>

The **SIZE** operator returns the value 0 when used on all other symbol types.

The **WIDTH unary operator**

The **WIDTH** operator returns the width in bits of a field in a record. The value depends on the type of symbol. The following table shows these types of symbols. You can’t use **WIDTH** for any other symbol types.

**Table 5.13 ** WIDTH values

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIDTH record_name</td>
<td>Returns the total number of bits reserved in the record definition.</td>
</tr>
<tr>
<td>WIDTH record_field_name</td>
<td>Returns the number of bits reserved for the field in the record definition.</td>
</tr>
<tr>
<td>WIDTH enum_name</td>
<td>Returns the number of bits required to represent the maximum value in the enum definition.</td>
</tr>
</tbody>
</table>

**MASK unary operator**

The **MASK** operator creates a mask from a bit field, where bits are set to 1 in the returned value and correspond to bits in a field that a symbol represents. The value
returned depends on the type of symbol, as shown in the following table. Note that you can’t use MASK on any other symbols.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASK record_name</td>
<td>Returns a mask where the bits reserved to represent bit fields in the record definition are 1, the rest 0.</td>
</tr>
<tr>
<td>MASK record_field_name</td>
<td>Returns a mask where the bits reserved for the field in the record definition are 1, the rest 0.</td>
</tr>
<tr>
<td>MASK enum_name</td>
<td>Returns a mask where the bits required to represent up to the maximum value present in the enum definition are 1, the rest 0.</td>
</tr>
</tbody>
</table>

**General arithmetic operators**

General arithmetic operators manipulate constants, symbol values, and the values of other general arithmetic operations. Common operators are addition, subtraction, multiplication, and division. Others operators are more specifically tailored for assembly language programming. We’ll discuss a little about all of these in the next few sections.

**Simple arithmetic operators**

Turbo Assembler supports the simple arithmetic operators shown in the following table.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+ expression</td>
<td>Expression.</td>
</tr>
<tr>
<td>- expression</td>
<td>Negative of expression.</td>
</tr>
<tr>
<td>expr1 + expr2</td>
<td>expr1 plus expr2.</td>
</tr>
<tr>
<td>expr1 – expr2</td>
<td>expr1 minus expr2.</td>
</tr>
<tr>
<td>expr1 * expr2</td>
<td>expr1 multiplied by expr2.</td>
</tr>
<tr>
<td>expr1 / expr2</td>
<td>expr1 divided by expr2 using signed integer division; note that expr2 cannot be 0 or greater than 16 bits in extent.</td>
</tr>
<tr>
<td>expr1 MOD expr2</td>
<td>Remainder of expr1 divided by expr2; same rules apply as for division.</td>
</tr>
</tbody>
</table>

**Logical arithmetic operators**

Logical operators let you perform Boolean algebra. Each of these operators performs in a bitwise manner; that is, the logical operation is performed one bit at a time. The following table shows the logical operators.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT expression</td>
<td>expression bitwise complemented</td>
</tr>
<tr>
<td>expr1 AND expr2</td>
<td>expr1 bitwise ANDed with expr2</td>
</tr>
<tr>
<td>expr1 OR expr2</td>
<td>expr1 bitwise ORed with expr2</td>
</tr>
<tr>
<td>expr1 XOR expr2</td>
<td>expr1 bitwise XORed with expr2</td>
</tr>
</tbody>
</table>
Bit shift operators
Shift operators move values left or right by a fixed number of bits. You can use them to do quick multiplication or division, or to access the value of a bitfield within a value. The following table lists the bit shift operators.

Table 5.17  Bit shift operators

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr1 SHL expr2</td>
<td>expr1 shifted left by expr2 bits (shifted right if expr2 is negative).</td>
</tr>
<tr>
<td>expr1 SHR expr2</td>
<td>expr1 shifted right by expr2 bits (shifted left if expr2 is negative).</td>
</tr>
</tbody>
</table>

Note that the SHL and SHR operators shift in 0s from the right or left to fill the vacated bits.

Comparison operators
Comparison operators compare two expressions to see if they’re equal or unequal, or if one is greater than or less than the other. The operators return a value of −1 if the condition is true, or a value of 0 if the condition is not true. The following table shows how you can use these operators.

Table 5.18  Comparison operators

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr1 EQ expr2</td>
<td>−1 if expr1 is equal to expr2; otherwise, 0.</td>
</tr>
<tr>
<td>expr1 NE expr2</td>
<td>−1 if expr1 is not equal to expr2; otherwise, 0.</td>
</tr>
<tr>
<td>expr1 GT expr2</td>
<td>−1 if expr1 is greater than expr2; otherwise, 0.</td>
</tr>
<tr>
<td>expr1 GE expr2</td>
<td>−1 if expr1 is greater than or equal expr2; otherwise, 0.</td>
</tr>
<tr>
<td>expr1 LT expr2</td>
<td>−1 if expr1 is less than expr2; otherwise, 0.</td>
</tr>
<tr>
<td>expr1 LE expr2</td>
<td>−1 if expr1 is less than or equal expr2; otherwise, 0.</td>
</tr>
</tbody>
</table>

EQ and NE treat expressions as unsigned numbers. For example, −1 EQ offffh has a value of −1 (unless you’ve selected the 80386 processor or used Ideal mode; then, −1 EQ offffffffh has a value of −1).

GT, GE, LT, and LE treat expressions as signed numbers. For example, 1 GE −1 has a value of −1, but 1 GE 0ffffh has a value of 0.

Setting the address subtype of an expression
Turbo Assembler provides operators that let you override or change the type of an expression. The following table lists these operators.

Table 5.19  Type override operators

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr1 PTR expr2</td>
<td>Converts expr2 to the type determined by expr1, where 0=UNKNOWN, 1=BYTE, 2=WORD, 4=DWORD, 6=FWORD, 8=QWORD, 10=TBYTE, 0ffff=NEAR, 0fffffff=FAR, all others=UNKNOWN; MASM mode only.</td>
</tr>
<tr>
<td>type PTR expression or type expression</td>
<td>Converts expression to the specified address subtype; Ideal mode only.</td>
</tr>
</tbody>
</table>
Table 5.19  Type override operators (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>type LOW expression</td>
<td>Converts expression to the specified address subtype. Type described must be smaller in size than the type of the expression; Ideal mode only.</td>
</tr>
<tr>
<td>type HIGH expression</td>
<td>Converts expression to the specified address subtype. Type described must be smaller in size than the type of the expression; the resulting address is adjusted to point to the high part of the object described by the address expression; Ideal mode only.</td>
</tr>
</tbody>
</table>

Here are some examples:

**IDEAL**

```
big DD 12345678h
MOV ax,[WORD big]      ;ax=5678h
MOV al,[BYTE PTR big]  ;al=78h
MOV ax,[WORD HIGH big] ;ax=1234h
MOV ax,[WORD LOW big]  ;ax=5678h
MOV al,[BYTE LOW WORD HIGH big] ;al = 3rd byte of big = 34h
```

**MASM**

```
MOV ax,2 PTR big       ;ax=5678h
MOV ax,WORD PTR big    ;ax=5678h (WORD has value 2)
```

**Obtaining the type of an expression**

In MASM mode, you can obtain the numeric value of the type of an expression by using the TYPE operator. (You can’t do this in Ideal mode, because types can never be described numerically). The syntax of the TYPE operator is

```
TYPE expression
```

The TYPE operator returns the size of the object described by the address expression, as follows:

Table 5.20  TYPE values

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>1</td>
</tr>
<tr>
<td>word</td>
<td>2</td>
</tr>
<tr>
<td>dword</td>
<td>4</td>
</tr>
<tr>
<td>pword</td>
<td>6</td>
</tr>
<tr>
<td>qword</td>
<td>8</td>
</tr>
<tr>
<td>tbyte</td>
<td>10</td>
</tr>
<tr>
<td>short</td>
<td>0ffffh</td>
</tr>
<tr>
<td>near</td>
<td>0ffffh</td>
</tr>
<tr>
<td>far</td>
<td>0ffe8h</td>
</tr>
<tr>
<td>struct/union</td>
<td>Size of a structure or union instance</td>
</tr>
<tr>
<td>table</td>
<td>Size of a table instance</td>
</tr>
<tr>
<td>proctype</td>
<td>Returns 0FFFFFh if the proctype describes a near procedure, or 0FFFEh for a far procedure</td>
</tr>
</tbody>
</table>

Here’s an example:
Overriding the segment part of an address expression

Address expressions have values consisting of a segment and an offset. You can specify the segment explicitly as a segment register, or as a segment or group value. (If you specify it as a group value, Turbo Assembler determines which segment register to use based on the values that the segment registers are ASSUMEd to be.) Use the following syntax to change the segment part of an address expression:

\[
expr1 : expr2
\]

This operation returns an address expression using the offset of \( expr2 \), and \( expr1 \) as a segment or group value. For example,

\[
VarPtr dd dgroup:memvar ; dgroup is a group
\]

\[
mov cl,es:[si+4] ; segment override ES
\]

Obtaining the segment and offset of an address expression

You can use the SEG and OFFSET operators to get the segment and offset of an expression. The SEG operator returns the segment value of the address expression. Here's its syntax:

\[
SEG expression
\]

Here is a code example:

\[
\begin{align*}
\text{DATASEG} \\
temp &\text{ DW } 0 \\
\text{CODESEG} \\
mov ax,SEG temp \\
mov ds,ax \\
\text{ASSUME ds:SEG temp}
\end{align*}
\]

The OFFSET operator returns the offset of the address expression. Its syntax follows:

\[
OFFSET expression
\]

Note that when you use the offset operator, be sure that the expression refers to the correct segment. For example, if you are using MASM mode and not using the simplified segmentation directives, the expression

\[
\text{VarPtr dd dgroup:memvar}
\]
OFFSET BUFFER ;buffer is a memory address

is not the same as

OFFSET DGROUP:BUFFER ;Dgroup is the group containing the segment that contains BUFFER

unless the segment that contains BUFFER happens to be the first segment in DGROUP.

In Ideal mode, addresses are automatically calculated relative to any group that a segment belongs to unless you override them with the : operator. In MASM mode, the same is true if you use the simplified segment directives. Otherwise, addresses are calculated relative to the segment an object is in, rather than any group.

**Creating an address expression using the location counter**

You can use the THIS operator to create an address expression that points to the current segment and location counter, and has a specific address subtype. You can use the following syntax in Ideal mode:

```
THIS type
```

The Ideal mode syntax lets you build an address expression from the current segment and location counter of the specified type.

You can use the next syntax in MASM mode:

```
THIS expression
```

The MASM mode syntax functions like the syntax in Ideal mode, but uses the numerical value of the expression to determine the type. These values are: 0=UNKNOWN, 1=BYTE, 2=WORD, 4=DWORD, 6=PWORD, 8=QWORD, 10=TBYTE, 0ffffh=NEAR, 0fffffh=FAR. For example,

```
ptrl LABEL WORD
ptr2 EQU THIS WORD ;similar to ptr1
```

**Determining the characteristics of an expression**

Sometimes, it’s useful to determine (within a macro) whether an expression has specific characteristics. The SYMTYPE and .TYPE operators let this happen.

The Ideal mode syntax:

```
SYMTYPE expression
```

The MASM mode syntax:

```
.TYPE expression
```

**Note** The SYMTYPE and .TYPE operators are exactly equivalent; however, .TYPE is available only in MASM mode, and you can use SYMTYPE only in Ideal mode.
SYMTYPE and .TYPE both return a constant value that describes the expression. This value is broken down into the bit fields shown in the following table.

**Table 5.21  Bit fields from SYMTYPE and .TYPE**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Expression is a program relative memory pointer.</td>
</tr>
<tr>
<td>1</td>
<td>Expression is a data relative memory pointer.</td>
</tr>
<tr>
<td>2</td>
<td>Expression is a constant value.</td>
</tr>
<tr>
<td>3</td>
<td>Expression uses direct addressing mode.</td>
</tr>
<tr>
<td>4</td>
<td>Expression contains a register.</td>
</tr>
<tr>
<td>5</td>
<td>Symbol is defined.</td>
</tr>
<tr>
<td>7</td>
<td>Expression contains an externally defined symbol.</td>
</tr>
</tbody>
</table>

The expression uses register indirection ([BX]) if bits 2 and 3 are both zero.

If Turbo Assembler can't evaluate the expression, SYMTYPE returns appropriate errors. .TYPE, however, will return a value in these situations (usually 0).

**Referencing structure, union, and table member offsets**

Structure, union, and table members are global variables whose values are the offset of the member within the structure, union, or table in MASM mode. In Ideal mode, however, members of these data types are considered local to the data type. The dot (.) operator lets you obtain the offsets of members. Here's the Ideal mode syntax:

```
expression . symbol
```

*expression* must represent an address of a structure, union, or table instance. *symbol* must be a member of the structure, union, or table. The dot operator returns the offset of the member within the structure.

MASM mode also contains a version of the dot operator. However, its function is similar to the + operator, and has the following syntax:

```
expr1 . expr2
```

**Describing the contents of an address**

Many instructions require you to distinguish between an address and the contents of an address. You can do this by using square brackets ([]). For example,

```
MOV AX, BX ;move BX into AX.
MOV AX, [BX] ;move contents of address BX into AX
```

Here's the general syntax for using square brackets:

```
[ expression ]
```

In MASM mode, the brackets are optional for expressions that are addresses. Complete addresses can't be used as an operand for any 80x86 instruction; rather, only the segment (obtained with the SEG operator) or the offset (obtained with the OFFSET operator) is used.
In Ideal mode, a warning is given when an expression is clearly an address, but no brackets are present. You can disable this warning (see Chapter 12 for further information). However, it's good programming practice to include these brackets.

**Implied addition**

In MASM mode, you can add expressions in several ways: using the addition operator (+), using the dot operator (.), or by implied addition (when expressions are separated by brackets or parentheses). For example,

```asm
MOV AX, 5[BX] ; contents of address BX+5
MOV AX, 5(XYZ) ; contents of address XYZ+5
```

Here's the general syntax for implicit addition:

```asm
expr1 [ expr2 ]
```

or

```asm
expr1 ( expr2 )
```

**Obtaining the high or low byte values of an expression**

You can use the HIGH and LOW operators on an expression to return its high and low byte values. This information can be useful in circumstances where, for example, only the high 8 bits of an address offset is required.

Here's the syntax of the HIGH and LOW operators:

```asm
HIGH expression
LOW expression
```

For example,

```asm
magic equ 1234h
mov cl, HIGH magic ; cl=12h
mov cl, LOW magic ; cl=34h
```

**Specifying a 16- or 32-bit expression**

When the currently selected processor is the 80386 or higher, Turbo Assembler provides two operators that let you control whether an expression is interpreted as a 16-bit value or as a 32-bit value: the SMALL and LARGE operators. Here are their syntaxes:

```asm
SMALL expression
LARGE expression
```

The SMALL operator flags the expression as representing a 16-bit value. LARGE flags it as representing a 32-bit value. These operators are particularly important when you program for an environment in which some segments are 32-bit and others are 16-bit. For example, the instruction

```asm
JMP [DWORD PTR ABC]
```

represents an indirect jump to the contents of the memory variable ABC. If you have enabled the 80386 processor, this instruction could be interpreted as either a far jump with a segment and 16-bit offset, or a near jump to a 32-bit offset. You can use SMALL or LARGE to remove the ambiguity, as follows:
JMP SMALL [DWORD PTR ABC]

This instruction causes Turbo Assembler to assemble the jump instruction so that the value read from ABC is interpreted as a 16-bit segment and 16-bit offset. Turbo Assembler then performs an indirect FAR jump.

When you use SMALL or LARGE within the address portion of an expression, the operators indicate that the address is a 32-bit address. For example,

JMP SMALL [LARGE DWORD PTR ABC]

indicates that a large 32-bit address describes the memory variable ABC, but its contents are interpreted as a 16-bit segment and 16-bit offset.
Choosing processor directives and symbols

The 8086 processor is actually only one of a family of processors known as the iAPx86 family. Members of this family include:

- The 8088 (which contains an 8-bit data bus), the 8086 (containing a 16-bit data bus)
- The 80186 and 80188 (like the 8086 and 8088 but contain additional instructions and run faster than their predecessors)
- The 80286 (which contains instructions for protected mode)
- The 80386 (which can process 16- and 32-bit data)
- The 80486 (an enhanced version of 80386 that runs even faster).
- The Pentium (an even faster version of the 80486).

Math coprocessors such as the 8087, 80287, and 80387 work with the iAPx86 family so that you can perform floating-point operations.

Turbo Assembler provides directives and predefined symbols that let you use the instructions included for particular processors. This chapter describes these directives and symbols.
iAPx86 processor directives

The iAPx86 family provides a variety of directives for you to use. In the following directives, note that those beginning with . are only available in MASM mode.

Table 6.1 Processor directives

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>P8086</td>
<td>Enables assembly of 8086 instructions only.</td>
</tr>
<tr>
<td>.8086</td>
<td>Enables assembly of the 8086 instructions and disables all instructions available only on the 80186, 80286, and 386 processors. It also enables the 8087 coprocessor instructions exactly as if the .8087 or 8087 had been issued.</td>
</tr>
<tr>
<td>P186</td>
<td>Enables assembly of 80186 instructions.</td>
</tr>
<tr>
<td>.186</td>
<td>Enables assembly of 80186 instructions.</td>
</tr>
<tr>
<td>P286</td>
<td>Enables assembly of all 80286 instructions.</td>
</tr>
<tr>
<td>P286N</td>
<td>Enables assembly of nonprivileged 80286 instructions.</td>
</tr>
<tr>
<td>P286P</td>
<td>Enables assembly of privileged 80286 instructions.</td>
</tr>
<tr>
<td>.286</td>
<td>Enables assembly of nonprivileged 80286 instructions. It also enables the 80287 numeric processor instructions exactly as if the .286 or P287 directive had been issued.</td>
</tr>
<tr>
<td>.286C</td>
<td>Enables assembly of nonprivileged 80286 instructions.</td>
</tr>
<tr>
<td>.286P</td>
<td>Enables assembly of all the additional instructions supported by the 80286 processor, including the privileged mode instructions. It also enables the 80287 numeric processor instructions exactly as if the .287 or P287 directive had been issued.</td>
</tr>
<tr>
<td>P386</td>
<td>Enables assembly of all 386 instructions.</td>
</tr>
<tr>
<td>P386N</td>
<td>Enables assembly of all nonprivileged 386 instructions.</td>
</tr>
<tr>
<td>P386P</td>
<td>Enables assembly of privileged 386 instructions.</td>
</tr>
<tr>
<td>.386</td>
<td>Enables assembly of the additional instructions supported by the 386 processor in nonprivileged mode. It also enables the 80387 numeric processor instructions exactly as if the .387 or P387 directive had been issued.</td>
</tr>
<tr>
<td>.386C</td>
<td>Enables assembly of 386 instructions.</td>
</tr>
<tr>
<td>.386P</td>
<td>Enables assembly of all the additional instructions supported by the 386 processor, including the privileged mode instructions. It also enables the 80387 numeric processor instructions exactly as if the .387 or P387 directive had been issued.</td>
</tr>
<tr>
<td>P486</td>
<td>Enables assembly of all i486 instructions.</td>
</tr>
<tr>
<td>P486N</td>
<td>Enables assembly of nonprivileged i486 instructions.</td>
</tr>
<tr>
<td>.486</td>
<td>Enables assembly of the additional instructions supported by the i486 processor in nonprivileged mode. It also enables the 387 numeric processor instructions exactly as if the .387 or P387 directive had been issued.</td>
</tr>
<tr>
<td>.486C</td>
<td>Enables assembly of all i486 instructions.</td>
</tr>
<tr>
<td>.486P</td>
<td>Enables assembly of all the additional instructions supported by the i486 processor, including the privileged mode instructions. It also enables the 80387 numeric processor instructions exactly as if the .387 or P387 directive had been issued.</td>
</tr>
<tr>
<td>.487</td>
<td>Enables assembly of 487 numeric processor instructions. This instruction works only in MASM mode.</td>
</tr>
<tr>
<td>P487</td>
<td>Enables assembly of 487 numeric processor instructions. This instruction works in both MASM and Ideal modes.</td>
</tr>
<tr>
<td>P586</td>
<td>Enables assembly of all Pentium instructions.</td>
</tr>
<tr>
<td>P586N</td>
<td>Enables assembly of nonprivileged Pentium instructions.</td>
</tr>
<tr>
<td>.586</td>
<td>Enables assembly of the additional instructions supported by the Pentium processor in nonprivileged mode.</td>
</tr>
</tbody>
</table>
Table 6.1  Processor directives (continued)

<table>
<thead>
<tr>
<th>Directive</th>

<td>Enables assembly of Pentium numeric processor instructions. This instruction works only in MASM mode.</td>
</tr>
<tr>
<td>P.587</td>
<td>Enables assembly of Pentium numeric processor instructions. This instruction works in both MASM and Ideal modes.</td>
</tr>
</tbody>
</table>

Note  The *Quick Reference Guide* contains details on the assembly instructions supported by each processor. For additional information, refer to the books listed in Chapter 1.

Predefined symbols

Two predefined symbols, @Cpu and @WordSize, can give you information about the type of processor you're using, or the size of the current segment. Here are descriptions of these symbols:

**@Cpu**

<table>
<thead>
<tr>
<th>Function</th>
<th>Numeric equate that returns information about current processor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remarks</td>
<td>The value returned by @Cpu encodes the processor type in a number of single-bit fields:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8086 instructions enabled</td>
</tr>
<tr>
<td>1</td>
<td>80186 instructions enabled</td>
</tr>
<tr>
<td>2</td>
<td>80286 instructions enabled</td>
</tr>
<tr>
<td>3</td>
<td>386 instructions enabled</td>
</tr>
<tr>
<td>4</td>
<td>486 instructions enabled</td>
</tr>
<tr>
<td>5</td>
<td>586 instructions enabled</td>
</tr>
<tr>
<td>7</td>
<td>Privileged instructions enabled (80286, 386, 486)</td>
</tr>
<tr>
<td>8</td>
<td>8087 numeric processor instructions</td>
</tr>
<tr>
<td>10</td>
<td>80287 numeric processor instructions</td>
</tr>
<tr>
<td>11</td>
<td>387 numeric processor instructions</td>
</tr>
</tbody>
</table>

The bits not defined here are reserved for future use. Mask them off when using @Cpu so that your programs will remain compatible with future versions of Turbo Assembler.

Since the 8086 processor family is upward compatible, when you enable a processor type with a directive like .286, the lower processor types (8086, 80186) are automatically enabled as well.
This equate only provides information about the processor you've selected at assembly
time using the .286 and related directives. The processor type and the CPU your
program is executing on at run time are not indicated.

Example
IFIPUSH = @Cpu AND 2 ;allow immediate push on 186 and above
IF IPUSH
PUSH 1234
ELSE
  mov ax,1234
  push ax
ENDIF

@WordSize

Function Numeric equate that indicates 16- or 32-bit segments
Remarks @WordSize returns 2 if the current segment is a 16-bit segment, or 4 if the segment is a
32-bit segment.
Example IF @WordSize EQ 4
  mov esp,0100h
ELSE
  mov sp,0100h
ENDIF

8087 coprocessor directives

The following table contains the available math coprocessor directives. Again, directives
beginning with a dot (.) work only in MASM mode.Turbo Assembler User's Guide

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| .287      | Enables assembly of all the 80287 numeric coprocessor instructions. Use this directive if you
           | know you'll never run programs using an 8087 coprocessor. This directive causes floating-
           | point instructions to be optimized in a manner incompatible with the 8087, so don't use it if
           | you want your programs to run using an 8087. |
| .387      | Enables assembly of all the 80387 numeric coprocessor instructions. Use this directive if you
           | know you'll never run programs using an 8087 coprocessor. This directive causes floating-
           | point instructions to be optimized in a manner incompatible with the 8087, so don't use it if
           | you want your programs to run using an 8087. |
| .487      | Enables assembly of all 80486 numeric instructions. |
| .587      | Enables assembly of all Pentium numeric instructions. |
| .8087     | Enables all the 8087 coprocessor instructions, and disables all those coprocessor instructions
           | available only on the 80287 and 80387 (the default). |
| P287      | Enables assembly of 80287 coprocessor instructions. |
| P387      | Enables assembly of 80387 coprocessor instructions. |
| P487      | Enables assembly of all 80486 numeric instructions. |

## Coprocessor emulation directives

If you need to use real floating-point instructions, you must use an 80x87 coprocessor. If your program has installed a software floating-point emulation package, you can use the EMUL directive to use it. (EMUL functions like /e.)

For example,

```plaintext
Finit ;real 80x87 coprocessor instruction
EMUL
Fsave BUF ;emulated instruction]
```

**Note**  Both EMUL and NOEMUL work in MASM and Ideal modes.

If you’re using an 80x87 coprocessor, you can either emulate floating-point instructions using EMUL, or force the generation of real floating-point instructions with the NOEMUL directive. Note that you can use EMUL and NOEMUL when you want to generate real floating-point instructions in one portion of a file, and emulated instructions in another.

Here’s an example using NOEMUL:

```plaintext
NOEMUL ;assemble real FP instructions
finit
EMUL ;back to emulation
```
Each processor in the 80x86 family has at least four segment registers: CS, DS, ES, and SS. These registers contain a segment value that describes a physical block of memory up to 64K in length (or up to 4 gigabytes on the 80386 and above). All addresses are calculated using one of these segment registers as a base value.

The meaning of the value stored in a segment register differs depending on whether the processor is using real mode (the ONLY mode available for the 8086 and 80186), where the segment value is actually a paragraph number, or protected mode, where a segment register contains a selector (which has no numerical significance).

The operating system or platform for a program determines whether the program operates in real mode or protected mode. If you use protected mode on the 80386 or 80486, the operating system also determines whether large (4 gigabyte) segments are permitted. Turbo Assembler supports all of these environments equally well.

In the general 80x86 model, programs are composed of one or more segments, where each segment is a physically distinct piece of code or data (or both) designed to be accessed by using a segment register. From this general scheme, many arbitrary organizations are possible. To apply some order to the chaos, some standard memory models have been devised. Since many high-level languages adhere to these conventions, your assembly language programs should also.

One obvious way to break up a program is to separate the program instructions from program data. You can classify each piece of program data as initialized (containing an initial value, such as text messages), or uninitialized (having no starting value). Turbo Assembler usually assigns uninitialized data to a separate segment so that it can be placed at the end of the program, reducing the size of the executable program file.

The stack is usually a fairly large portion of the uninitialized data. It's also special because the SS and SP registers are usually initialized automatically to the stack area...
when you execute a program. Thus, the standard memory models treat the stack as a separate segment.

You can also combine segments into groups. The advantage of using groups is that you can use the same segment value for all the segments in the group. For example, initialized data, uninitialized data, and stack segments are often combined into a group so that the same segment value can be used for all of the program data.

This chapter describes how to use models and segments in your code and the directives that make this possible.

The MODEL directive

The MODEL directive lets you specify one of several standard segmentation models for your program. You can also use it to specify a language for the procedures in your program.

Here's the syntax for the MODEL directive:

```
MODEL [model_modifier] memory_model [code_segment_name]
[, [language_modifier] language ]
[, model_modifier]
```

In MASM mode, you can use the same syntax, but with the .MODEL directive.

memory_model and model_modifier specify the segmentation memory model to use for the program.

The standard memory models available in Turbo Assembler have specific segments available for:

- code
- initialized data
- uninitialized data
- far initialized data
- far uninitialized data
- constants
- stack

The code segment usually contains a module's code (but it can also contain data if necessary). Initialized data and constants are treated separately for compatibility with some high level languages. They contain data such as messages where the initial value is important. Uninitialized data and stack contain data whose initial value is unimportant. Far initialized data is initialized data that is not part of the standard data segment, and can be reached only by changing the value of a segment register. A module can have more than one far initialized data segment. Far uninitialized data is similar, except that it contains uninitialized data instead of initialized data.

The specific memory model determines how these segments are referenced with segment registers, and how they are combined into groups (if at all). When writing a program, you should keep these segments separate, regardless of the program's size.
Then, you can select the proper model to group the segments together. If you keep these segments separate and your program grows, you can choose a larger model.

The memory model is the only required parameter of the MODEL directive. Table 7.1 describes each of the standard memory models.

The model modifier field lets you change certain aspects of the model. You can specify more than one model modifier, if you wish. Table 7.2 shows the available model modifiers.

Note that you can specify the model modifier in two places, for compatibility with MASM 5.2. If you don’t use a model specifier, Turbo Assembler assumes the NEARSTACK modifier, and USE32 (if the 80386 or 80486 processor is selected). Unless otherwise specified, DOS is the platform.

Use the optional code_segment_name field in the large code models to override the default name of the code segment. Normally, this is the module name with _TEXT appended to it.

</tbody>
</table>

The `language` and `language_modifier` together specify the default procedure calling conventions, and the default style of the prolog and epilog code present in each procedure. They also control how to publish symbols externally for the linker to use. Turbo Assembler will automatically generate the procedure entry and exit code that is proper for procedures using any of the following interfacing conventions: PASCAL, C, CPP (C++), SYSCALL, STDCALL, BASIC, FORTRAN, PROLOG, and NOLANGUAGE. If you don’t specify a language, Turbo Assembler assumes the default language to be NOLANGUAGE.

Use `language_modifier` to specify additional prolog and epilog code when you write procedures for Windows, or for the Borland Overlay loader. These options are: NORMAL, WINDOWS, ODDNEAR and ODDFAR. If you don’t specify an option, Turbo Assembler assumes the default to be NORMAL.

Also note that you can override the default language and `language_modifier` when you define a procedure. See Chapter 10 for further details.

You can additionally override the default language when you publish a symbol.

**Symbols created by the MODEL directive**

When you use the `MODEL` directive, Turbo Assembler creates and initializes certain variables to reflect the details of the selected model. These variables can help you write code that’s model independent, through the use of conditional assembly statements. See Chapter 15 for information about how you can use variables to alter the assembly process.

**The @Model symbol**
The `@Model` symbol contains a representation of the model currently in effect. It is defined as a text macro with any of the following values:

- 1 = tiny model is in effect
- 2 = small or flat
- 3 = compact
- 4 = medium
- 5 = large
The @32Bit symbol
The @32Bit symbol contains an indication of whether segments in the currently specified model are declared as 16 bit or 32 bit. The symbol has a value of 0 if you specified 16-bit segments in the MODEL directive, or 1 if you indicated 32-bit segments.

The @CodeSize symbol
The @CodeSize text macro symbol indicates the default size of a code pointer in the current memory model. It’s set to 0 for the memory models that use NEAR code pointers (TINY, SMALL, FLAT, COMPACT, TPASCAL), and 1 for memory models that use FAR code pointers (all others).

The @DataSize symbol
The @DataSize text macro symbol indicates the default size of a data pointer in the current memory model. It’s set to 0 for the memory models using NEAR data pointers (TINY, SMALL, FLAT, MEDIUM), 1 for memory models that use FAR data pointers (COMPACT, LARGE, TPASCAL), and 2 for models using huge data pointers (HUGE and TCHUGE).

The @Interface symbol
The @Interface symbol provides information about the language and operating system selected by the MODEL statement. This text macro contains a number whose bits represent the following values:

<table>
<thead>
<tr>
<th>Value in bits 0-6</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NOLANGUAGE</td>
</tr>
<tr>
<td>1</td>
<td>C</td>
</tr>
<tr>
<td>2</td>
<td>SYSCALL</td>
</tr>
<tr>
<td>3</td>
<td>STDCALL</td>
</tr>
<tr>
<td>4</td>
<td>PASCAL</td>
</tr>
<tr>
<td>5</td>
<td>FORTRAN</td>
</tr>
<tr>
<td>6</td>
<td>BASIC</td>
</tr>
<tr>
<td>7</td>
<td>PROLOG</td>
</tr>
<tr>
<td>8</td>
<td>CPP</td>
</tr>
</tbody>
</table>

Bit 7 can have a value of 0 for DOS/Windows, or 1 for 32-bit flat models (Windows 95, Windows NT, or OS/2).

For example, the value 01h for @Interface shows that you selected the DOS operating system and the C language.
Simplified segment directives

Once you select a memory model, you can use simplified segment directives to begin the individual segments. You can only use these segmentation directives after a MODEL directive specifies the memory model for the module. Place as many segmentation directives as you want in a module; Turbo Assembler combines all the pieces with the same name to produce one segment (exactly as if you had entered all the pieces at once after a single segmentation directive). Table 7.4 contains a list of these directives.

Table 7.4  Simplified segment directives

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CODESEG [name]</td>
<td>Begins or continues the module's code segment. For models whose code is FAR, you can specify a name that is the actual name of the segment. Note that you can generate more than one code segment per module in this way.</td>
</tr>
<tr>

<td>Same as DATASEG. MASM mode only.</td>
</tr>
<tr>
<td>CONST</td>
<td>Begins or continues a module's constant data segment. Constant data is always NEAR and is equivalent to initialized data.</td>
</tr>
<tr>
<td>.CONST</td>
<td>Same as CONST. MASM mode only.</td>
</tr>
<tr>
<td>UDATASEG</td>
<td>Begins or continues a module's NEAR or default uninitialized data segment. Be careful to include only uninitialized data in this segment or the resulting executable program will be larger than necessary. See Chapter 12 for a description of how to allocate uninitialized data.</td>
</tr>
<tr>
<td>.DATA?</td>
<td>Same as UDATASEG. MASM mode only.</td>
</tr>
<tr>
<td>STACK [size]</td>
<td>Begins or continues a module's stack segment. The optional size parameter specifies the amount of stack to reserve, in words. If you don't specify a size, Turbo Assembler assumes 200h words (1Kbytes). In MASM mode, any labels, code, or data following the STACK statement will not be considered part of the stack segment. Ideal mode, however, reserves the specified space, and leaves the stack segment open so that you can add labels or other uninitialized data. You usually only need to use the stack directive if you are writing a stand-alone assembly language program; most high-level languages will create a stack for you.</td>
</tr>
<tr>
<td>.STACK [size]</td>
<td>Same as STACK. MASM mode only.</td>
</tr>
<tr>
<td>FARDATA [name]</td>
<td>Begins or continues a FAR initialized data segment of the specified name. If you don't specify a name, Turbo Assembler uses the segment name FAR_DATA. You can have more than one FAR initialized data segment per module.</td>
</tr>
<tr>
<td>.FARDATA [name]</td>
<td>Same as FARDATA. MASM mode only.</td>
</tr>
<tr>
<td>UFARDATA [name]</td>
<td>Begins or continues a FAR uninitialized data segment of the specified name. If you don't specify a name, Turbo Assembler uses segment name FAR_BSS. You can have more than one FAR uninitialized data segment per module.</td>
</tr>
<tr>
<td>.FARDATA? [name]</td>
<td>Same as UFARDATA. MASM mode only.</td>
</tr>
</tbody>
</table>

Note  See Appendix A if you need to know the actual names, class names, and alignments of the segments created with the simplified segment directives.
Symbols created by the simplified segment directives
When you use the simplified segment directives, they create variables that reflect the details of the selected segment, just as the MODEL directive does. See Chapter 15 for further information. The following table lists these symbols.

Table 7.5 Symbols from simplified segment directives

<table>
<thead>
<tr>
<th>Symbol name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>the segment or group that CS is assumed to be</td>
</tr>
<tr>
<td>@data</td>
<td>the segment or group that DS is assumed to be</td>
</tr>
<tr>
<td>@fardata</td>
<td>the current FARDATA segment name</td>
</tr>
<tr>
<td>@fardata?</td>
<td>the current UFARDATA segment name</td>
</tr>
<tr>
<td>@curseg</td>
<td>the current segment name</td>
</tr>
<tr>
<td>@stack</td>
<td>the segment or group that SS is assumed to be</td>
</tr>
</tbody>
</table>

The STARTUPCODE directive

The STARTUPCODE directive provides initialization code appropriate for the current model and operating system. It also marks the beginning of the program. Here’s its syntax:

```
STARTUPCODE
```

or

```
.STARTUP;(MASM mode only)
```

STARTUPCODE initializes the DS, SS, and SP registers. For the SMALL, MEDIUM, COMPACT, LARGE, HUGE, and TPASCAL models, Turbo Assembler sets DS and SS to @data, and SP to the end of the stack. For TINY and TCHUGE models, the STARTUPCODE directive doesn’t change the segment registers.

The @Startup symbol

The @Startup symbol is placed at the beginning of the startup code that the STARTUPCODE directive generates. It is a near label marking the start of the program.

The EXITCODE directive

You can use the EXITCODE directive to produce termination code appropriate for the current operating system. You can use it more than once in a module, for each desired exit point. Here’s its syntax:

```
EXITCODE [return_value_expr]
```

You can use the following syntax only in MASM mode:

```
.EXIT [return_value_expr]
```

The optional return_value_expr describes the number to be returned to the operating system. If you don’t specify a return value, Turbo Assembler assumes the value in the AX register.
Defining generic segments and groups

Most applications can use segments created using the standard models. These standard models, however, are limited in their flexibility. Some applications require full control over all aspects of segment generation; generic segment directives provide this flexibility.

The SEGMENT directive

The SEGMENT directive opens a segment. All code or data following it will be included in the segment, until a corresponding ENDS directive closes the segment.

The Ideal mode syntax for the SEGMENT directive is:

\[ \text{SEGMENT } \text{name [attributes]} \]

You can use the following syntax for MASM mode:

\[ \text{name SEGMENT [attributes]} \]

\text{name} is the name of the segment. You should name segments according to their usages. See Appendix B for examples of segment names.

You can open and close a segment of the same name many times in a single module. In this case, Turbo Assembler concatenates together the sections of the segment in the order it finds them. You only need to specify the \text{attributes} for the segment the first time you open the segment.

\text{attributes} includes any and all desired segment attribute values, for each of the following:

- segment combination attribute
- segment class attribute
- segment alignment attribute
- segment size attribute
- segment access attribute

Note Turbo Assembler processes attribute values from left to right.

Segment combination attribute

The segment combination attribute tells the linker how to combine segments from different modules that have the same name. The following table lists the legal values of the segment combination attribute. Note that if you don’t specify the combine type, Turbo Assembler assumes PRIVATE.

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIVATE</td>
<td>Segment will not be combined with any other segments of the same name outside of this module.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Segment will be concatenated with other segments of the same name outside of this module to form a single contiguous segment.</td>
</tr>
</tbody>
</table>
Table 7.6  Segment combination attribute (continued)

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY</td>
<td>Same as PUBLIC. Segment will be concatenated with other segments of the same name outside this module to form a single contiguous segment, used as the default stack. The linker initializes values for the initial SS and SP registers so that they point to the end of these segments.</td>
</tr>
<tr>
<td>COMMON</td>
<td>Locates this segment and all other segments with the same name at the same address. All segments of this name overlap shared memory. The length of the resulting common segment is the length of the longest segment from a single module.</td>
</tr>
<tr>
<td>VIRTUAL</td>
<td>Defines a special kind of segment that must be declared inside an enclosing segment. The linker treats it as a common area and attaches it to the enclosing segment. The virtual segment inherits its attributes from the enclosing segment. The assume directive considers a virtual segment to be a part of its parent segment; in all other ways, a virtual segment is a common area that is combined across modules. This permits the sharing of static data that comes into many modules from included files.</td>
</tr>
<tr>
<td>AT xxx</td>
<td>Locates the segment at the absolute paragraph address that the expression xxx specifies. The linker doesn't emit any data or code for AT segments. Use AT to allow symbolic access to fixed memory locations, such as the display screen or ROM areas.</td>
</tr>
<tr>
<td>UNINIT</td>
<td>Produces a warning message to let you know that you have inadvertently written initialized data to uninitialized data segments. For example, you can specify the following to produce a warning message: BSS SEGMENT PUBLIC WORD UNINIT 'BSS'. To disable this warning message, use the NOWARN UNI directive. You can reenable the message by using the WARN UNI directive.</td>
</tr>
</tbody>
</table>

Segment class attribute

The segment class attribute is a quoted string that helps the linker determine the proper ordering of segments when it puts together a program from modules. The linker groups together all segments with the same class name in memory. A typical use of the class name is to group all the code segments of a program together (usually the class CODE is used for this). Data and uninitialized data are also grouped using the class mechanism.

Segment alignment attribute

The segment alignment attribute tells the linker to ensure that a segment begins on a specified boundary. This is important because data can be loaded faster on the 80x86 processors if it’s properly aligned. The following table lists legal values for this attribute.

Table 7.7  Segment alignment attribute

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>No special alignment; start segment on the next available byte.</td>
</tr>
<tr>
<td>WORD</td>
<td>Start segment on the next word-aligned address.</td>
</tr>
<tr>
<td>DWORD</td>
<td>Start segment on the next doubleword-aligned address.</td>
</tr>
<tr>
<td>PARA</td>
<td>Start segment on the next paragraph (16-byte aligned) address.</td>
</tr>
<tr>
<td>PAGE</td>
<td>Start segment on the next page (256-byte aligned) address.</td>
</tr>
<tr>
<td>MEMPAGE</td>
<td>Start segment on the next memory page (4Kb aligned) address.</td>
</tr>
</tbody>
</table>

Turbo Assembler assumes the PARA alignment if you don’t specify the alignment type.
Segment size attribute
If the currently selected processor is the 80386, segments can be either 16 bit or 32 bit. The segment size attribute tells the linker which of these you want for a specific segment. The following table contains the legal attribute values.

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>USE16</td>
<td>Segment is 16 bit. A 16-bit segment can contain up to 64K of code and/or data.</td>
</tr>
<tr>
<td>USE32</td>
<td>Segment is 32 bit. A 32-bit segment can contain up to 4 gigabytes of code and/or data.</td>
</tr>
</tbody>
</table>

Turbo Assembler assumes the USE32 value if you selected the 80386 processor in MASM mode. In Ideal mode, Turbo Assembler assumes USE16 by default.

Segment access attribute
For any segment in protected mode, you can control access so that certain kinds of memory operations are not permitted. (Note that this feature is currently supported only by the Phar Lap linker. You must generate object code compatible with it using the /op switch if you want to be able to use the segment access attribute.) The segment access attribute tells the linker to apply specific access restrictions to a segment.

The following table lists the legal values for this attribute.

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXECONLY</td>
<td>the segment is executable only</td>
</tr>
<tr>
<td>EXECREAD</td>
<td>the segment is readable and executable</td>
</tr>
<tr>
<td>READONLY</td>
<td>the segment is readable only</td>
</tr>
<tr>
<td>READWRITE</td>
<td>the segment is readable and writable</td>
</tr>
</tbody>
</table>

The Phar Lap linker assumes that the segment is meant to run in protected mode if you select any of these attributes, or if you select the USE32 attribute. Turbo Assembler assumes the READONLY attribute if you selected the USE32 attribute but did not specify any of these four attributes.

The ENDS directive
You can use the ENDS directive to close a segment so that no further data is emitted into it. You should use the ENDS directive to close any segments opened with the SEGMENT directive. Segments opened using the simplified segment directives don’t require the ENDS directive.

Here’s the syntax of the ENDS directive:

```assembly
ENDS [name]
```

For MASM mode only, you can use the following syntax:

```assembly
name ENDS
```
name specifies the name of the segment to be closed. Turbo Assembler will report an error message if name doesn’t agree with the segment currently open. If you don’t specify a name, Turbo Assembler assumes the currently-open segment.

**The GROUP directive**

You can use the GROUP directive to assign segments to groups. A group lets you specify a single segment value to access data in all segments in the group.

Here’s the Ideal mode syntax for the GROUP directive:

```
GROUP name segment_name [, segment_name...]  
```

You can use the following syntax for MASM mode:

```
name GROUP segment_name [, segment_name...]  
```

name is the name of the group. segment_name is the name of a segment you want to assign to that group.

**The ASSUME directive**

A segment register must be loaded with the correct segment value for you to access data in a segment. Often, you must do this yourself. For example, you could use the following code to load the address of the current far data segment into DS:

```
MOV AX, @fardata  
MOV DS, AX  
```

When a program loads a segment value into a segment register, you use that segment register to access data in the segment. It rapidly becomes tiring (and is also poor programming practice) to specify a specific segment register every time you process data in memory.

**Note**

Use the ASSUME directive to tell Turbo Assembler to associate a segment register with a segment or group name. This allows Turbo Assembler to be “smart enough” to use the correct segment registers when data is accessed.

In fact, Turbo Assembler uses the information about the association between the segment registers and group or segment names for another purpose as well: in MASM mode, the value that the CS register is ASSUMEd to be is used to determine the segment or group a label belongs to. Thus, the CS register must be correctly specified in an ASSUME directive, or Turbo Assembler will report errors every time you define a label or procedure.

Here’s the syntax of the ASSUME directive:

```
ASSUME segreg : expression [, segreg : expression ]  
or
ASSUME NOTHING  
```

segreg is one of CS, DS, ES or SS registers. If you specify the 80386 or 80486 processor, you can also use the FS and GS segment registers. expression can be any expression that
The NOTHING keyword cancels the association between the designated segment register and any segment or group name.

**ASSUME NOTHING** removes associations between all segment registers and segment or group names.

You can use the ASSUME directive whenever you modify a segment register, or at the start of a procedure to specify the assumptions at that point. In practice, ASSUMEs are usually used at the beginning of a module and occasionally within it. If you use the **MODEL** statement, Turbo Assembler automatically sets up the initial ASSUMEs for you.

If you don’t specify a segment in an ASSUME directive, its ASSUMEd value is not changed.

For example, the following code shows how you can load the current initialized far data segment into the DS register, access memory in that segment, and restore the DS register to the data segment value.

```assembly
MOV AX, @fardata
MOV DS, AX
ASSUME DS: @fardata
MOV BX, <far_data_variable>
MOV AX, @data
MOV DS, AX
ASSUME DS: @data
```

### Segment ordering

The linker arranges and locates all segments defined in a program’s modules. Generally, the linker starts with the order in which it encounters the segments in a program’s modules. You can alter this order using mechanisms such as segment combination and segment classing.

There are other ways to affect the way the linker arranges segments in the final program. For example, the order in which segments appear in a module’s source can be changed. There are also directives that affect segment ordering. Descriptions of these follow.

#### Changing a module’s segment ordering

The order of segments in each module determines the starting point for the linker’s location of segments in the program. In MASM 1.0, 2.0, and 3.0, segments were passed to the linker in alphabetical order. Turbo Assembler provides directives (in MASM mode only) that let you reproduce this behavior.

Note that these directives have the same function as the **/A** and **/S** command line switches. See Chapter 2 for further details.
The .ALPHA directive

The .ALPHA directive specifies alphabetic segment ordering. This directive tells Turbo Assembler to place segments in the object file in alphabetical order (according to the segment name). Its syntax is

```
.ALPHA
```

The .SEQ directive

The .SEQ directive specifies sequential segment ordering, and tells Turbo Assembler to place segments in the object file in the order in which they were encountered in the source file. Since this is the default behavior of the assembler, you should usually use the .SEQ directive only to override a previous .ALPHA or a command line switch. Here’s the syntax of .SEQ:

```
.SEQ
```

DOS ordering of segments: the DOSSEG directive

Normally, the linker arranges segments in the sequential order it encounters them during the generation of the program. When you include a DOSSEG directive in any module in a program, it instructs the linker to use standard DOS segment ordering instead. The linker defines this convention to mean the following arrangement of segments in the final program:

- segments having the class name CODE (typically code segments)
- segments that do not have class name CODE and are not part of DGROUP
- segments that are part of DGROUP in the following order:
  1. segments not of class BSS or STACK (typically initialized data)
  2. segments of class BSS (typically uninitialized data)
  3. segments of class STACK (stack space)

The segments within DGROUP are located in the order in which they were defined in the source modules.

Note  DOSSEG is included in TASM for backward compatibility only. It is recommended that you do not use the DOSSEG directive in new assembly programs. In addition, do not use the DOSSEG directive if you’re interfacing assembly programs with C programs.

Changing the size of the stack

A procedure’s prolog and epilog code manipulates registers that point into the stack. On the 80386 or 80486 processor, the stack segment can be either 16 bits or 32 bits. Turbo Assembler therefore must know the correct size of the stack before it can generate correct prolog and epilog code for a procedure.

The stack size is automatically selected if you selected a standard model using the MODEL statement.
Turbo Assembler provides directives that can set or override the default stack size for procedure prolog and epilog generation. The following table lists these directives.

**Table 7.10  Stack size modification directives**

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLSTACK</td>
<td>Indicates that the stack is 16 bit</td>
</tr>
<tr>
<td>LARGESTACK</td>
<td>Indicates that the stack is 32 bit</td>
</tr>
</tbody>
</table>
Defining data types symbolically helps you write modular code. You can easily change or extend data structures without having to rewrite code by separating the definition of a data type from the code that uses it, and allowing symbolic access to the data type and its components.

Turbo Assembler supports as many or more symbolic data types than most high-level languages. This chapter describes how to define various kinds of data types.

Defining enumerated data types

An enumerated data type represents a collection of values that can be stored in a certain number of bits. The maximum value stored determines the actual number of bits required.

Here is the Ideal mode syntax for declaring an enumerated data type:

```plaintext
ENUM name [enum_var [,enum_var...]]
```

You can use the following syntax in MASM mode:

```plaintext
name ENUM [enum_var [,enum_var...]]
```

The syntax of each `enum_var` is:

```plaintext
var_name [=value]
```

Turbo Assembler will assign a value equal to that of the last variable in the list plus one if `value` isn’t present when you assign the specified value to the variable `var_name`. Values can’t be relative or forward referenced. Variables that `ENUM` created are redefinable numeric variables of global scope.

**Warning!** If you use the same variable name in two enumerated data types, the first value of the variable will be lost, and errors could result.
name is the name of the **ENUM** data type. You can use it later in the module to obtain a variety of information about the values assigned to the variables detailed. See Chapter 5 for information about using enumeration data type names in Turbo Assembler expressions.

**Note** You can also use enumerated data type names to create variables and allocate memory. See Chapter 12 for details.

Enumerated data types are redefinable. You can define the same name as an enumerated data type more than once in a module.

Turbo Assembler provides a multiline syntax for enumerated data type definitions requiring a large number of variables. The symbol { starts the multiline definition, and the symbol } stops it.

The Ideal mode syntax follows:

```assembler
ENUM name [enum_var [,enum_var...]] { 
    [enum_var [,enum_var...]]
    ...
    [enum_var [,enum_var...]]
}
```

You can use the following syntax in MASM mode:

```assembler
name ENUM [enum_var [,enum_var...]] {
    [enum_var [,enum_var...]]
    ...
    [enum_var [,enum_var...]]
}
```

For example, all of the following enumerated data type definitions are equivalent:

```assembler
foo ENUM f1,f2,f3,f4 ;Original version
foo ENUM 
    f1
    f2
    f3
    f4
;Multiline version
}
foo ENUM f1,f2, {   ;More compact multiline version
    f3,f4
}
```

**Note** Turbo Assembler doesn’t recognize any pseudo ops inside the multiline enumerated data type definition.

### Defining bit-field records

A record data type represents a collection of bit fields. Each bit field has a specific width (in bits) and an initial value. The record data type width is the sum of the widths of all the fields.

You can use record data types to compress data into a form that’s as compact as possible. For example, you can represent a group of 16 flags (which can be either ON or...
OFF) as 16 individual bytes, 16 individual words, or as a record containing 16 1-bit fields (the efficient method).

Here's the Ideal mode syntax for declaring a record data type:

```plaintext
RECORD name [rec_field [,rec_field...]]
```

The MASM mode syntax is:

```plaintext
name RECORD [rec_field [,rec_field...]]
```

Each `rec_field` has the following syntax:

```plaintext
field_name : width_expression [=value]
```

`field_name` is the name of a record field. Turbo Assembler will allocate a bit field of the width `width_expression` for it. `value` describes the initial value of the field (the default value used when an instance of the record is created). Values and width expressions can't be relative or forward referenced. Record field names are global in scope and can't be redefined.

`name` is the name of the record data type. You can use it later in the module to obtain a variety of information about the record data type. You can also use the names of individual record fields to obtain information. See Chapter 5 for details about how to obtain information from record data type names and record field names using Turbo Assembler expressions.

You can redefine record data types, and define the same name as a record data type more than once in a module.

**Note** You can also use record data type names to create variables and allocate memory. See Chapter 12 for details.

Turbo Assembler provides special support for record fields that represent flags and enumerated data types. Additional and extended instructions provide efficient access to record fields. Chapter 13 describes this concept further.

For record data type definitions requiring a large number of fields, Turbo Assembler provides a multiline syntax similar to that for enumerated data types.

For example, all of the following record data type definitions are equivalent:

```plaintext
foo RECORD f1:1,f2:2,f3:3,f4:4 ;Original version
foo RECORD 
  f1:1
  f2:2
  f3:3
  f4:4
} ;Multiline version
foo RECORD f1:1,f2:2,
  f3:3,f4:4
} ;More compact multiline version
```

**Note** Turbo Assembler does not recognize any pseudo ops inside the multiline record data type definition.
Defining structures and unions

Structures and unions let you mix and match various types. A structure in Turbo Assembler is a data type that contains one or more data elements called members. Structures differ from records because structure members are always an integral number of bytes, while records describe the breakdown of bit fields within bytes. The size of a structure is the combined size of all data elements within it.

Unions are similar to structures, except that all of the members in a union occupy the same memory. The size of a union is the size of its largest member. Unions are useful when a block of memory must represent one of several distinct possibilities, each with different data storage requirements.

Turbo Assembler lets you fully nest structures and unions within one another, but this can become complicated. For example, you could have a structure member that is really a union. A union could also have a full structure as each member.

Opening a structure or union definition

Use the following Ideal mode syntaxes to open a structure or union data type definition:

```
STRUC name  or  UNION name
```

You can use the following MASM mode syntaxes to do the same thing:

```
name STRUC or name UNION
```

'name' is the name of the structure or union data type.

Turbo Assembler considers all data or code emitted between the time a structure or union data type definition is opened and the time a corresponding ENDS directive is encountered to be part of that structure or union data type.

Turbo Assembler treats structure and union data type names as global but redefinable. You can define the same name as a structure or union data type more than once in a module.

Specifying structure and union members

Turbo Assembler includes data one line at a time in structures or unions. To allocate data and create members in a structure or union definition, use the same directives as those for allocating data and creating labels in an open segment. For example,

```
member1   DW 1
```

is equally valid in a segment or in a structure definition. In a segment, this statement means "reserve a word of value 1, whose name is member1." In a structure or union definition, this statement means "reserve a word of initial value 1, whose member name is member1."

You can use the initial value for a structure member if an instance of the structure or union is allocated in a segment or a structure. If you don’t intend to allocate structure
instances this way, the initial value of the structure member is not important. You can use the data value ? (the uninitialized data symbol) to indicate this.

Turbo Assembler allows all methods of allocating data with a structure definition, including instances of other structures, unions, records, enumerated data types, tables, and objects. For more information on how to allocate data, see Chapter 12.

MASM and Ideal modes treat structure member names differently. In MASM mode, structure member names are global and can’t be redefined. In Ideal mode, structure member names are considered local to a structure or union data type.

**Defining structure member labels with LABEL**

The LABEL directive lets you create structure members without allocating data. Normally, the LABEL directive establishes a named label or marker at the point it’s encountered in a segment. LABEL directives found inside structure definitions define members of the structure. Here’s the syntax of the LABEL directive:

```
LABEL name complex_type
```

In MASM mode only, you can use the following syntax:

```
name LABEL complex_type
```

`name` is the name of the structure member. `type` is the desired type for the structure member. It can be any legal type name. See Chapter 5 for a description of the available type specifiers.

**Aligning structure members**

You can use the ALIGN directive within structure definitions to align structures members on appropriate boundaries. For example,

```
ALIGN 4 ;DWORD alignment
member dd ? ;member will be DWORD aligned
```

**Closing a structure or union definition**

You must close the structure or union definition after you define all structure or union members. Use the ENDS directive to do this.

ENDS has the following syntax in Ideal mode:

```
ENDS [name]
```

In MASM mode, you can use the following syntax:

```
name ENDS
```

`name`, if present, is the name of the currently open structure or union data type definition. If `name` is not present, the currently open structure or union will be closed.

You can also use the ENDS directive to close segments. This is not a conflict, because you can’t open a segment inside a structure or union definition.
Nesting structures and unions

Turbo Assembler lets you nest the STRUC, UNION, and ENDS directives inside open structure and union data type definitions to control the offsets assigned to structure members.

In a structure, each data element begins where the previous one ended. In a union, each data element begins at the same offset as the previous data element. Allowing a single data element to consist of an entire union or structure provides enormous flexibility and power. The following table contains descriptions of STRUC, UNION, and ENDS.

<table>
<thead>
<tr>
<th>Table 8.1 STRUC, UNION, and ENDS directives</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directive</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>STRUC</td>
</tr>
<tr>
<td>UNION</td>
</tr>
<tr>
<td>ENDS</td>
</tr>
</tbody>
</table>

For example, the composite has five members in the following structure/union data definition:

```assembly
CUNION STRUC
CTYPE DB ?
    UNION ;Start of union
    ;If CTYPE=0, use this...
    STRUC
    CT0PAR1 DW 1
    CT0PAR2 DB 2
    ENDS
    ;If CTYPE=1, use this...
    STRUC
    CT1PAR1 DB 3
    CT1PAR2 DD 4
    ENDS
    ENDS ;End of union
ENDS ;End of structure data type
```

The following table lists these members.
Table 8.2  Block members

<table>
<thead>
<tr>
<th>Member</th>
<th>Type</th>
<th>Offset</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTYPES</td>
<td>Byte</td>
<td>0</td>
<td>? (uninitialized)</td>
</tr>
<tr>
<td>CTOPAR1</td>
<td>Word</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>CTOPAR2</td>
<td>Byte</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>CTIPAR1</td>
<td>Byte</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>CTIPAR2</td>
<td>Dword</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

The length of this structure/union is 6 bytes.

Including one named structure within another

Turbo Assembler provides a way of incorporating an entire existing structure or union data type, including member names, into an open structure definition to assist in the inheritance of objects. It treats the incorporated structure or union as if it were nested inside the open structure or union definition at that point. In this way, incorporating a structure or union into another is intrinsically different from including an instance of a structure or union in another; an instance includes only initialized or uninitialized data, while incorporation includes data, structure, and member names.

Here's the Ideal mode syntax:

```plaintext
STRUC struc_name fill_parameters
```

You can use the following syntax in MASM mode:

```plaintext
struc_name STRUC fill_parameters
```

Use a statement of this form only inside a structure or union definition. `struc_name` is the name of the previously defined structure or union that is to be included. `fill_parameters` represents the changes you want to make to the initial (default) values of the included structure's members. A ? keyword indicates that all of the incorporated structure's members should be considered uninitialized. Otherwise, the syntax for the `fill_parameters` field is:

```plaintext
{ [member_name [=expression] [,member_name [=expression] ...]] }
```

`member_name` is the name of any member of the included structure whose initial value should be changed when it's included. `expression` is the value you want to change it to. If you have `expression`, then the initial value for that member of the structure will be unchanged when it is included. If you specify a ? keyword for the expression field, that member's initial value will be recorded as uninitialized when it's included.

Since structure member names are global in MASM mode, they are not redefined when you copy a structure. Thus, including a structure within another is most useful in MASM mode when you do it at the beginning of the structure or union you're defining.

Usually, when you create an instance of a union, you would have to make sure that only one of the union's members contains initialized data. (See Chapter 12 for details.) Since incorporating a structure in another does not involve creating an instance, this restriction does not apply. More than one member of an included union can contain initialized data. For example,
FOO STRUC
ABC    DW 1
DEF    DW 2
UNION
A1    DB '123'
A2    DW ?
ENDS
ENDS

UNION
Al DB '123'
A2 DW 2
ENDS
ENDS

The definition of structure FOO2 in the previous example is equivalent to the following nested structure/union:

FOO2 STRUC

FOO STRUC (A1=2) ;Incorporates struc FOO into struc FOO2, with override
;Note that both A1 and A2 are initialized by
;default in FOO2!

GHI DB 3
ENDS

Note that when an instance of the structure FOO2 is made, be sure that only one value in the union is initialized.

Using structure names in expressions

Once you define a structure or union, information about the structure or union is available in many ways. You can use both the structure or union data type name and a structure member name to obtain information using Turbo Assembler expressions. See Chapter 5 for further information.

Defining tables

A table data type represents a collection of table members. Each member has a specific size (in bytes) and an initial value. A table member can be either virtual or static. A virtual member of a table is assigned an offset within the table data type; space is reserved for it in any instance of the table. A static member does not have an offset; space isn’t reserved for it in an instance of the table.

The size of the table data type as a whole is the sum of the sizes of all of the virtual members.
Table data types represent method tables, used in object-oriented programming. An object usually has a number of methods associated with it, which are pointers to procedures that manipulate instances of the object. Method procedures can either be called directly (static methods) or indirectly, using a table of method procedure pointers (virtual methods).

You can use the following Ideal mode syntax for declaring a table data type:

```
TABLE name [table_member [,table_member...]]
```

The following syntax works only in MASM mode:

```
name TABLE [table_member [,table_member...]]
```

Here's the syntax of each `table_member` field:

- `table_name`

  or

  ```
  [VIRTUAL] member_name [[count1_expression]]
  [: complex_type [:count2_expression]] [= expression ]
  ```

`table_name` is the name of an existing table data type whose members are incorporated entirely in the table you define. Use this syntax wherever you want inheritance to occur.

`member_name` is the name of the table member. The optional `VIRTUAL` keyword indicates that the member is virtual and should be assigned to a table offset.

`complex_type` can be any legal complex type expression. See Chapter 5 for a detailed description of the valid type expressions.

If you don’t specify a `complex_type` field, Turbo Assembler assumes it to be WORD (DWORD is assumed if the currently selected model is a 32-bit model).

`count2_expression` specifies how many items of this type the table member defines. A table member definition of

```
foo TABLE VIRTUAL tmp:DWORD:4
```

defines a table member called `tmp`, consisting of four doublewords.

The default value for `count2_expression` is 1 if you don’t specify it. `count1_expression` is an array element size multiplier. The total space reserved for the member is `count2_expression` times the length specified by the `memtype` field, times `count1_expression`. The default value for `count1_expression` is also 1 if you don’t specify one. `count1_expression` multiplied by `count2_expression` specifies the total count of the table member.

**Note** Table member names are local to a table in Ideal mode, but are global in scope in MASM mode.

`name` is the name of the table data type. You can use it later in the module to get a variety of information about the table data type. You can also use the names of individual table members to obtain information. See Chapter 5 for further information.

Table data types are redefinable. You can define the same name as a table data type more than once in a module.
You can also use table data type names to create variables and allocate memory. See Chapter 12 for details.

Alternatively, Turbo Assembler provides a multiline syntax for table data type definitions requiring a large number of members. This syntax is similar to that of enumerated data type definitions. Here's an example:

```asm
foo TABLE t1:WORD, t2:WORD, t3:WORD, t4:WORD ;Original version
foo TABLE {
    t1:WORD
    t2:WORD
    t3:WORD
    t4:WORD
}
foo TABLE t1:WORD, t2:WORD, {
    t3:WORD, t4:WORD}
```

**Overriding table members**

If you declare two or more members of the same name as part of the same table data type, Turbo Assembler will check to be sure that their types and sizes agree. If they don't, it will generate an error. Turbo Assembler will use the last initial value occurring in the table definition for the member. In this way, you can override the initial value of a table after it is incorporated into another. For example,

```asm
FOO TABLE VIRTUAL MEM1:WORD=MEM1PROC, VIRTUAL MEM2:WORD=MEM2PROC
FOO2 TABLE FOO, VIRTUAL MEM1:WORD=MEM3PROC ;Overrides inherited ;MEM1
```

**Defining a named type**

Named types represent simple or complex types. You can use the `TYPEDEF` directive to define named types. Here's the Ideal mode syntax:

```
TYPEDEF type_name complex_type
```

The MASM mode syntax is:

```
type_name TYPEDEF complex_type
```

`complex_type` describes any type or multiple levels of pointer indirection. See Chapter 5 for further information about complex types. `type_name` is the name of the specified type.

When you use a named type in an expression, it functions as if it were a simple type of the appropriate size. For example,

```asm
MOV ax, word ptr [bx] ;Simple statement;
foo TYPEDEF near ptr byte ;FOO is basically a word
MOV ax, foo ptr [bx] ;so this works too
```
Defining a procedure type

For Turbo Assembler version 3.2 or higher, you can use a user-defined data type (called a procedure type) to describe the arguments and calling conventions of a procedure. Turbo Assembler treats procedure types like any other types; you can use it wherever types are allowed. Note that since procedure types don’t allocate data, you can’t create an instance of a procedure type.

Use the **PROC_TYPE** directive to create a procedure type. Here is the Ideal mode syntax:

```
PROCEDURE name [procedure description]
```

The MASM mode syntax is:

```
name PROCEDURE [procedure_description]
```

`procedure_description` is similar to the language and argument specification for the **PROC** directive. Its syntax is:

```
[[language_modifier] language] [distance] [argument_list]
```

specify `language_modifier`, `language`, and `distance` exactly the same way you would for the corresponding fields in the **PROC** directive. For more information about the **PROC** directive, see Chapter 10.

Use the following form for `argument_list`:

```
argument [,argument] ...
```

An individual argument has the following syntax:

```
[argname] [[count1_expression]]:complex_type [:count2_expression]
```

`complex_type` is the data type of the argument. It can be either a simple type or a pointer expression.

**Note** See Chapter 5 for a discussion of the syntax of complex types.

`count2_expression` specifies how many items of this type the argument defines. Its default value is 1, except for BYTE arguments. Those arguments have a default count of 2, since you can’t **PUSH** a byte value onto the 80x86 stack.

In procedure types whose calling convention permits variable-length arguments (like C), `count2_expression` (for the last argument) can be the special keyword `?`, which indicates that the procedure caller will determine the size of the array. The type `UNKNOWN` also indicates a variable-length parameter.

The name of each argument is optional, but `complex_type` is required because procedure types are used mainly for type checking purposes. The names of the arguments don’t have to agree, but the types must.

Defining an object

An object consists of both a data structure and a list of methods that correspond to the object. Turbo Assembler uses a structure data type to represent the data structure
associated with an object, and a table data type to represent the list of methods associated with an object.

An extension to the STRUC directive lets you define objects. The Ideal mode syntax follows:

```
STRUC name [modifiers] [parent_name] [METHOD
    [table_member_1 [,table_member...]]]
structure_members
ENDS [name]
```

You can use the following syntax in MASM mode:

```
name STRUC [modifiers] [parent_name] [METHOD
    [table_member_1 [,table_member...]]]
structure_members
[name] ENDS
```

`name` is the name of the object. `parent_name` is the optional name of the parent object. (Turbo Assembler explicitly supports only single inheritance.) The parent object’s structure data will automatically be included in the new object’s structure data, and the parent object’s table of methods will be included in the new object’s table of methods as well.

Each `table_member` field describes a method name and method procedure associated with the object. The syntax of a `table_member` field is exactly the same as in a table definition.

`structure_members` describe any additional structure members you want within the object’s data structure. These are formatted exactly the same as in an open structure definition.

The optional `modifiers` field can be one or more of the following keywords:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>GLOBAL</td>
<td>Causes the address of the virtual method table (if any) to be published globally.</td>
</tr>
<tr>
<td>NEAR</td>
<td>Forces the virtual table pointer (if any) to be an offset quantity, either 16 or 32 bits, depending on whether the current model is USE16 or USE32.</td>
</tr>
<tr>
<td>FAR</td>
<td>Forces the virtual table pointer (if any) to be a segment and offset quantity, either 32 or 48 bits, depending on whether the current model is USE16 or USE32.</td>
</tr>
</tbody>
</table>

The size of the virtual table pointer (if any) depends on whether data in the current model is addressed as NEAR or FAR if you don’t specify a modifier.

**The TBLPTR directive**

Inherent in the idea of objects is the concept of the virtual method table. An instance of this table exists once for any object having virtual methods. The data structure for any object having virtual methods also must contain a pointer to the virtual method table for that object. Turbo Assembler automatically provides a virtual method table pointer in
an object’s data structure (if required) and if you don’t specify it explicitly using the TBLPTR directive.

You should use the TBLPTR directive within an object data structure definition. TBLPTR lets you explicitly locate the virtual table pointer wherever you want. Here’s its syntax:

```
TBLPTR
```

The size of the pointer that TBLPTR reserves is determined by whether the current model is USE16 or USE32, and what modifiers you used in the object definition.

**Symbols defined by the extended STRUC directive**

The extended STRUC directive defines or uses several symbols, which reflect the object being defined. The following table shows these symbols.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>@Object</td>
<td>A text macro containing the name of the current object</td>
</tr>
<tr>
<td>@Table_&lt;object_name&gt;</td>
<td>A table data type containing the object’s method table</td>
</tr>
<tr>
<td>@Tableaddr_&lt;object_name&gt;</td>
<td>A label describing the address of the object’s virtual method table</td>
</tr>
</tbody>
</table>
Setting and using the location counter

The location counter keeps track of the current address as your source files assemble. This lets you know where you are at any time during assembly of your program. Turbo Assembler supplies directives that let you manipulate the location counter to move it to a desired address.

Labels are the names used for referring to addresses within a program. Labels are assigned the value of the location counter at the time they are defined. Labels let you give names to memory variables and the locations of particular instructions.

This chapter discusses the available directives for manipulating the location counter, and declaring labels at the current location counter.

The $ location counter symbol

The predefined symbol $ represents the current location counter. The location counter consists of two parts: a segment, and an offset. The location counter is the current offset within the current segment during assembly.

The location counter is an address that is incremented to reflect the current address as each statement in the source file is assembled. As an example,

```assembly
helpMessage  DB   'This is help for the program.'
helpLength   = $ - helpMessage
```

Once these two lines are assembled, the symbol helpLength will equal the length of the help message.
Location counter directives

Turbo Assembler provides several directives for setting the location counter. The next few sections describe these directives. Note that all of these directives work in both MASM and Ideal modes.

The ORG directive

You can use the ORG directive to set the location counter in the current segment. ORG has the following syntax:

```
ORG expression
```

expression can’t contain any forward-referenced symbol names. It can either be a constant or an offset from a symbol in the current segment or from the current location counter.

You can back up the location counter before data or code that has already been emitted into a segment. You can use this to go back and fill in table entries whose values weren’t known at the time the table was defined. Be careful when using this technique; you might accidentally overwrite something you didn’t intend to.

You can use the ORG directive to connect a label with a specific absolute address. The ORG directive can also set the starting location for .COM files. Here’s an example of how to use ORG:

```asm
; This program shows how to create a structure and macro for
; declaring instances of the structure, that allows additional
; elements to be added to the linked list without regard to
; other structures already declared in the list. If the macro
; is invoked in a section of code that is between two other
; instances of the structure, the new structure will automatically
; be inserted in the linked list at that point without your
; needing to know the names of the previous or next
; structure variables. Similarly, using the macro
; at the end of the program easily adds new structures to the
; linked list without regard for the name of the previous
; element.
; The macro also maintains variables that point to the first
; and last elements of the linked list.

db 56 dup (0)

; Give a string to put in the info element of this structure
makea third,"Hello"

end
The EVEN and EVENDATA directives

You can use the **EVEN** directive to round up the location counter to the next even address. **EVEN** lets you align code for efficient access by processors that use a 16-bit data bus. It does not improve performance for processors that have an 8-bit data bus.

**EVENDATA** aligns evenly by advancing the location counter without emitting data, which is useful for uninitialized segments. Both **EVEN** and **EVENDATA** will cause Turbo Assembler to generate a warning message if the current segment's alignment isn't strict enough.

If the location counter is odd when an **EVEN** directive appears, Turbo Assembler places a single byte of a **NOP** instruction in the segment to make the location counter even. By padding with a **NOP**, **EVEN** can be used in code segments without causing erroneous instructions to be executed at run time. This directive has no effect if the location is already even.

**Note**

In code segments, NOPs are emitted. In data segments, zeros are emitted.

Similarly, if the location counter is odd when an **EVENDATA** directive appears, Turbo Assembler emits an uninitialized byte.

An example of using the **EVEN** directive follows:

```assembly
EVEN
@@A: lodsb
    xor bl,al ;align for efficient access
    loop @@A
```

Here's an example of using the **EVENDATA** directive:

```assembly
EVENDATA
VAR1 DW 0 ;align for efficient 8086 access
```

The ALIGN directive

You'll use the **ALIGN** directive to round up the location counter to a power-of-two address. **ALIGN** has the following syntax:

```
ALIGN boundary
```

*boundary* must be a power of two.

Turbo Assembler inserts **NOP** instructions into the segment to bring the location counter up to the desired address if the location counter is not already at an offset that is a multiple of *boundary*. This directive has no effect if the location counter is already at a multiple of *boundary*.

You can't reliably align to a boundary that's more strict than the segment alignment in which **ALIGN** appears. The segment's alignment is specified when the segment is first started with the **SEGMENT** directive.

For example, if you've defined a segment with

```assembly
CODE SEGMENT PARA PUBLIC
```
you can then say ALIGN 16 (same as PARA) but not ALIGN 32, since that’s more strict
than the alignment that PARA indicated in the SEGMENT directive. ALIGN generates
a warning if the segment alignment isn’t strict enough.

The following example shows how you can use the ALIGN directive:

```
ALIGN 4 ; align to DWORD boundary for 386
BigNum DD 12345678
```

Defining labels

Labels let you assign values to symbols. There are three ways of defining labels:

- using the : operator
- using the LABEL directive
- using the :: operator (from MASM 5.1)

The : operator

The : operator defines a near code label, and has the syntax

```
name:
```

where name is a symbol that you haven’t previously defined in the source file. You can
place a near code label on a line by itself or at the start of a line before an instruction. You
usually would use a near code label as the destination of a JMP or CALL instruction
from within the same segment.

The code label will only be accessible from within the current source file unless you use
the PUBLIC directive to make it accessible from other source files.

This directive functions the same as using the LABEL directive to define a NEAR label;
for example, A: is the same as A LABEL NEAR. For example,

```
A:
```

is the same as

```
A LABEL NEAR
```

Here’s an example of using the : operator.

```
jne A ; skip following function
inc si
A: ; jne goes here
```

The LABEL directive

You’ll use the LABEL directive to define a symbol with a specified type. Note that the
syntax is different for Ideal and MASM modes. In Ideal mode, specify

```
LABEL name complex_type
```

In MASM mode, use the following:
name LABEL complex_type

*name* is a symbol that you haven’t previously defined in the source file. *complex_type* describes the size of the symbol and whether it refers to code or data. See Chapter 5 for further information about complex types.

The label is only accessible from within the current source file, unless you use `PUBLIC` to make it accessible from other source files.

You can use `LABEL` to access different-sized items than those in the data structure; the following example illustrates this concept.

```assembly
WORDS LABEL WORD ;access "BYTES" as WORDS
BYTES DB 64 DUP (0)
mov WORDS[2],1 ;write WORD of 1
```

### The `::` directive

The `::` directive lets you define labels with a scope beyond the procedure you’re in. This differs from the `:` directive in that labels defined with `:` have a scope of only within the current procedure. Note that `::` is different from `:` only when you specify a language in the `.MODEL` statement.

**Note**   The `::` directive only works when you’re using MASM 51.
Turbo Assembler lets you declare procedures in many ways. This chapter discusses NEAR and FAR procedures, declaring procedure languages using arguments and variables in procedures, preserving registers, nesting procedures, declaring method procedures for objects, and declaring procedure prototypes. You can find more information about how to call language procedures in Chapter 13.

Procedure definition syntax

You can use the PROC directive to declare procedures. Here's its Ideal mode syntax:

\[
\text{PROC name [[language modifier] language] [distance]}
\[
\text{[ARG argument_list] [RETURNS item_list]}
\[
\text{[LOCAL argument_list]}
\[
\text{[USES item_list]}
\[
\text{;}
\[
\text{ENDP [name]}
\]
\]
\]
\]
\]
\]
\]

Use the following syntax in MASM mode:

\[
\text{name PROC [[language modifier] language] [distance]}
\[
\text{[ARG argument_list] [RETURNS item_list]}
\[
\text{[LOCAL argument_list]}
\[
\text{[USES item_list]}
\[
\text{;}
\[
\text{[name] ENDP}
\]
\]
\]
\]
\]

Turbo Assembler also accepts MASM syntax for defining procedures. For more information on MASM syntax, see Chapter 3.

If you're using Turbo Assembler version T310 or earlier, use the following Ideal mode syntax:
PROC [[language modifier] language] name [distance]
[ARG argument_list] [RETURNS item_list]
[LOCAL argument_list]
[USES item_list]
;
ENDP

**Note**  Unless you specify version T310 or earlier, the Ideal mode syntax is no longer allowed in MASM mode.

Note that the only difference between the older versions of Turbo Assembler and the later versions is that *language* and *language_modifier* have been moved to follow the procedure name to facilitate consistent function prototyping.

### Declaring NEAR or FAR procedures

**NEAR** procedures are called with a near call, and contain a near return; you must call them only from within the same segment in which they're defined. A near call pushes the return address onto the stack, and sets the instruction pointer (IP) to the offset of the procedure. Since the code segment (CS) is not changed, the procedure must be in the same segment as the caller. When the processor encounters a near return, it pops the return address from the stack and sets IP to it; again, the code segment is not changed.

**FAR** procedures are called with a far call and contain far returns. You can call **FAR** procedures from outside the segment in which they're defined. A far call pushes the return address onto the stack as a segment and offset, and then sets CS:IP to the address of the procedure. When the processor encounters a far return, it pops the segment and offset of the return address from the stack and sets CS:IP to it.

The currently selected model determines the default distance of a procedure. For tiny, small, and compact models, the default procedure distance is **NEAR**. For all other models, **FAR** is the default. If you don't use the simplified segmentation directives, the default procedure distance is always **NEAR**. Note that you can specify **NEAR** or **FAR** as an argument to the **MODEL** statement. See Chapter 7 for more information.

You can override the default distance of a procedure by specifying the desired distance in the procedure definition. To do this, use the **NEAR** or **FAR** keywords. These keywords override the default procedure distance, but only for the current procedure. For example,

```assembly
:;
MODEL TINY ;default distance near
:
;test1 is a far procedure
test1 PROC FAR
;body of procedure
RET ;this will be a far return
ENDP
```
;test2 is by default a near procedure
test2 PROC
    ;body of procedure
    RET ;this will be a near return
ENDP

The same RET mnemonic is used in both NEAR and FAR procedures; Turbo Assembler uses the distance of the procedure to determine whether a near or far return is required. Similarly, Turbo Assembler uses the procedure distance to determine whether a near or far call is required to reference the procedure:

CALL test1;this is a far call
CALL test2;this is a near call

When you make a call to a forward referenced procedure, Turbo Assembler might have to make multiple passes to determine the distance of the procedure. For example,

test1 PROC NEAR
    MOV ax,10
    CALL test2
    RET
test1 ENDP
test2 PROC FAR
    ADD ax,ax
    RET
test2 ENDP

When Turbo Assembler reaches the “call test2” instruction during the first pass, it has not yet encountered test2, and therefore doesn’t know the distance. It assumes a distance of NEAR, and presumes it can use a near call.

When it discovers that test2 is in fact a FAR procedure, Turbo Assembler determines that it needs a second pass to correctly generate the call. If you enable multiple passes (with the /m command-line switch), a second pass will be made. If you don’t enable multiple passes, Turbo Assembler will report a “forward reference needs override” error.

You can specify the distance of forward referenced procedures as NEAR PTR or FAR PTR in the call to avoid this situation (and to reduce the number of passes).

test1 PROC NEAR
    MOV ax,10
    CALL FAR PTR test2
    RET
test1 ENDP

The previous example tells Turbo Assembler to use a far call, so that multiple assembler passes aren’t necessary.
Declaring a procedure language

You can easily define procedures that use high-level language interfacing conventions in Turbo Assembler. Interfacing conventions are supported for the NOLANGUAGE (Assembler), BASIC, FORTRAN, PROLOG, C, CPP (C++), SYSCALL, STDCALL, and PASCAL languages.

Turbo Assembler does all the work of generating the correct prolog (procedure entry) and epilog (procedure exit) code necessary to adhere to the specified language convention.

You can specify a default language as a parameter of the MODEL directive. See Chapter 7 for further details. If a default language is present, all procedures that don’t otherwise specify a language use the conventions of the default language.

To override the default language for an individual procedure, include the language name in the procedure definition. You can specify a procedure language by including a language identifier keyword in its declaration. For example, a definition in MASM mode for a PASCAL procedure would be

```plaintext
... pascalproc PROC PASCAL FAR ;procedure body pascalproc ENDP ...
```

Turbo Assembler uses the language of the procedure to determine what prolog and epilog code is automatically included in the procedure’s body. The prolog code sets up the stack frame for passed arguments and local variables in the procedure; the epilog code restores the stack frame before returning from the procedure.

Turbo Assembler automatically inserts prolog code into the procedure before the first instruction of the procedure, or before the first “label:” tag.

Prolog code does the following:
- Saves the current BP on the stack.
- Sets BP to the current stack pointer.
- Adjusts the stack pointer to allocate local variables.
- Saves the registers specified by USES on the stack.

Turbo Assembler automatically inserts epilog code into the procedure at each RET instruction in the procedure (if there are multiple RETs, the epilog code will be inserted multiple times). Turbo Assembler also inserts epilog code before any object-oriented method jump (see Chapter 4).

Epilog code reverses the effects of prolog code in the following ways:
- Pops the registers specified by USES off the stack.
- Adjusts the stack pointer to discard local arguments.
- Pops the stored BP off the stack.
- Adjusts the stack to discard passed arguments (if the language requires it) and returns.
The last part of the epilog code, discarding passed arguments, is performed only for those languages requiring the procedure to discard arguments (for example, BASIC, FORTRAN, PASCAL). The convention for other languages (C, C++, PROLOG) is to leave the arguments on the stack and let the caller discard them. SYSCALL behaves like C++. For the STDCALL language specification, C++ calling conventions are used if the procedure has variable arguments. Otherwise, PASCAL calling conventions are used.

**Note**  Turbo Assembler always implements the prolog and epilog code using the most efficient instructions for the language and the current processor selected.

Turbo Assembler doesn’t generate prolog or epilog code for NOLANGUAGE procedures. If such procedures expect arguments on the stack, you must specifically include the prolog and epilog code yourself.

In general, the language of a procedure affects the procedure in the manner shown in the following figure.

**Figure 10.1** How language affects procedures

<table>
<thead>
<tr>
<th>Language:</th>
<th>None</th>
<th>Basic</th>
<th>Fortran</th>
<th>Pascal</th>
<th>C</th>
<th>CPP</th>
<th>Prolog</th>
</tr>
</thead>
<tbody>
<tr>

<td>CALLER</td>
</tr>
</tbody>
</table>

You can use the /la command-line switch to include procedure prolog and epilog code in your listing file. This lets you see the differences between the languages. See Chapter 13 for further information.

**Specifying a language modifier**

Language modifiers tell Turbo Assembler to include special prolog and epilog code in procedures that interface with Windows or the VROOM overlay manager. To use them, specify one before the procedure language in the model directive, or in the procedure header. Valid modifiers are NORMAL, WINDOWS, ODDNEAR, and ODDFAR.

Additionally, you can specify a default language modifier as a parameter of the MODEL directive. If a default language modifier exists, all procedures that don’t otherwise specify a language modifier will use the conventions of the default. See Chapter 7 for more information.

Include the modifier in the procedure definition to specify the language modifier for an individual procedure. For example,

```plaintext
: sample PROC WINDOWS PASCAL FAR
     ;procedure body
ENDP
:
```
Note If you don't specify a language modifier, Turbo Assembler uses the language modifier specified in the MODEL statement. Turbo Assembler will generate the standard prolog or epilog code for the procedure if there isn't a MODEL statement, or if NORMAL is specified.

If you've selected the WINDOWS language modifier, Turbo Assembler generates prolog and epilog code that lets you call the procedure from Windows. Turbo Assembler generates special prolog and epilog code only for FAR Windows procedures. You can't call NEAR procedures from Windows, so they don't need special prolog or epilog code. Procedures called by Windows typically use PASCAL calling conventions. For example,

```
winproc PROC WINDOWS PASCAL FAR
ARG @@hwnd:WORD,@@mess:WORD,@@wparam:WORD,@@lparam:DWORD
;body of procedure
ENDP
```

Note Refer to your Windows documentation for more information on Windows procedures.

The ODDNEAR and ODDFAR language modifiers are used in connection with the VROOM overlay manager. VROOM has two modes of operation: oddnear and oddfar. You can use the /la switch option on the Turbo Assembler command line to see the prolog and epilog code that these language modifiers produce.

### Defining arguments and local variables

Turbo Assembler passes arguments to higher-level language procedures in stack frames by pushing the arguments onto the stack before the procedure is called. A language procedure reads the arguments off the stack when it needs them. When the procedure returns, it either removes the arguments from the stack at that point (the Pascal calling convention), or relies on the caller to remove the arguments (the C calling convention).

The ARG directive specifies, in the procedure declaration, the stack frame arguments passed to procedures. Arguments are defined internally as positive offsets from the BP or EBP registers.

The procedure's language convention determines whether or not the arguments will be assigned in reverse order on the stack. You should always list arguments in the ARG statement in the same order they would appear in a high-level declaration of the procedure.

The LOCAL directive specifies, in the procedure declaration, the stack frame variables local to procedures. Arguments are defined internally as negative offsets from the BP or EBP register.

Allocate space for local stack frame variables on the stack frame by including procedure prolog code, which adjusts the stack pointer downward by the amount of space required. The procedure's epilog code must discard this extra space by restoring the stack pointer. (Turbo Assembler automatically generates this prolog code when the procedure obeys any language convention other than NOLANGUAGE.)
Remember that Turbo Assembler assumes that any procedure using stack frame arguments will include proper prolog code in it to set up the BP or EBP register. (Turbo Assembler automatically generates prolog code when the procedure obeys any language convention other than NOLANGUAGE). Define arguments and local variables with the ARG and LOCAL directives even if the language interfacing convention for the procedure is NOLANGUAGE. No prolog or epilog code will automatically be generated, however, in this case.

**ARG and LOCAL syntax**

Here’s the syntax for defining the arguments passed to the procedure:

```
ARG argument [,argument] ... [=symbol]
[RETURNS argument [,argument]]
```

To define the local variables for the procedure, use the following:

```
LOCAL argument [,argument] ... [=symbol]
```

An individual argument has the following syntax:

```
argname [([count1_expression]) [: complex_type [:count2_expression]]
```

`complex_type` is the data type of the argument. It can be either a simple type, or a complex pointer expression. See Chapter 5 for more information about the syntax of complex types.

If you don’t specify a `complex_type` field, Turbo Assembler assumes `WORD`. It assumes `DWORD` if the selected model is a 32-bit model.

`count2_expression` specifies how many items of this type the argument defines. An argument definition of

```
ARG tmp:DWORD:4
```

defines an argument called `tmp`, consisting of 4 double words.

The default value for `count2_expression` is 1, except for arguments of type `BYTE`. Since you can’t push a byte value, `BYTE` arguments have a default count of 2 to make them word-sized on the stack. This corresponds with the way high-level languages treat character variables passed as parameters. If you really want to specify an argument as a single byte on the stack, you must explicitly supply a `count2_expression` field of 1, such as

```
ARG realbyte:BYTE:1
```

`count1_expression` is an array element size multiplier. The total space reserved for the argument on the stack is `count2_expression` times the length specified by the `argtype` field, times `count1_expression`. The default value for `count1_expression` is 1 if it is not specified. `count1_expression` times `count2_expression` specifies the total count of the argument.

For Turbo Assembler versions 3.2 or later, you can specify `count2_expression` using the `?` keyword to indicate that a variable number of arguments are passed to the procedure. For example, an argument definition of

```
ARG tmp:WORD:?'
```

defines an argument called `tmp`, consisting of a variable number of words.
? must be used as the last item in the argument list. Also, you can use ? only in procedures that support variable-length arguments (such as procedures that use the C calling conventions).

If you end the argument list with an equal sign (=) and a symbol, Turbo Assembler will equate that symbol to the total size of the argument block in bytes. If you are not using Turbo Assembler's automatic handling of high level language interfacing conventions, you can use this value at the end of the procedure as an argument to the RET instruction. Notice that this causes a stack cleanup of any pushed arguments before returning (this is the Pascal calling convention).

The arguments and variables are defined within the procedure as BP-relative memory operands. Passed arguments defined with ARG are positive offset from BP; local variables defined with LOCAL are negative offset from BP. For example,

```assembly
func1 PROC NEAR
ARG a:WORD,b:DWORD:4,c:BYTE=d
LOCAL x:DWORD,y:WORD:2=z
```

defines a as [bp+4], b as [bp+6], c as [bp+14], and d as 20; x is [bp–2], y is [bp–6], and z is 8.

The scope of ARG and LOCAL variable names

All argument names specified in the procedure header, whether ARGs (passed arguments), RETURNs (return arguments), or LOCALs (local variables), are global in scope unless you give them names prepended with the local symbol prefix.

The LOCALS directive enables locally scoped symbols. For example,

```assembly
:
LOCALS
:
      LOCALS
test1 PROC PASCAL FAR
ARG @@a:WORD,@@b:DWORD,@@c:BYTE
LOCAL @@x:WORD,@@y:DWORD
      MOV ax,@@a
      MOV @@x,ax
      LES di,@@b
      MOV WORD ptr @@y,di
      MOV WORD ptr @@y+2,es
      MOV @@c,'a'
      RET
ENDP
test2 PROC PASCAL FAR
ARG @@a:DWORD,@@b:BYTE
LOCAL @@x:WORD
      LES di,@@a
      MOV ax,es:[di]
      MOV @@x,ax
      CMP al,@@b
```
jz @@dn
MOV @@x,0
@@dn: MOV ax,@@x
RET
ENDP

Since this example uses locally scoped variables, the names exist only within the body of the procedure. Thus, test2 can reuse the argument names @@a, @@b, and @@x. See Chapter 11 for more information about controlling the scope of symbols.

**Preserving registers**

Most higher-level languages require that called procedures preserve certain registers. You can do this by pushing them at the start of the procedure, and popping them again at the end of it.

Turbo Assembler can automatically generate code to save and restore these registers as part of a procedure's prolog and epilog code. You can specify these registers with the `USES` statement. Here's its syntax:

```
USES item [,item] ...
```

*item* can be any register or single-token data item that can legally be pushed or popped. There is a limit of eight items per procedure. For example,

```
myproc PROC PASCAL NEAR
ARG @@source:DWORD,@@dest:DWORD,@@count:WORD
USES cx,si,di,foo
  MOV cx,@@count
  MOV foo,@@count
  LES di,@@dest
  LDS si,@@source
  REP MOVSB
RE
ENDP
```

See Chapter 18 for information about what registers are normally preserved.

`USES` is only available when used with procedures that have a language interfacing convention other than NOLANGUAGE.

**Defining procedures using procedure types**

You can use a procedure type (defined with `PROCTYPE`) as a template for the procedure declaration itself. For example,
footype PROCTYPE pascal near :word, :dword,:word

: foo PROC footype ;pascal near procedure
arg a1:word,a2:dword,a3:word ;an error would occur if
;arguments did not match
;those of footype

When you declare a procedure using a named procedure description, the number and
types of the arguments declared for PROC are checked against those declared by
PROCTYPE. The procedure description supplies the language and distance of the
procedure declaration.

### Nested procedures and scope rules

All procedures have global scope, even if you nest them within another procedure. For example,

```asm
::
test1 PROC FAR
  ;some code here
  CALL test2
  ;some more code here
  RET

test2 PROC NEAR
  ;some code here
  RET ;near return

test2 ENDP

test1 ENDP
::
```

In this example, it's legal to call test1 or test2 from outside the outer procedure.

If you want to have localized subprocedures, use a locally scoped name. For example,

```asm
::
LOCALS

test1 PROC FAR  ;some code here
  RET
@@test2 PROC NEAR ;some code here
  RET
@@test2 ENDP

test1 ENDP
::
```

In this case, you can only access the procedure @@test2 from within the procedure test1.
In fact, there can be multiple procedures named @@test2 as long as no two are within
the same procedure. For example, the following is legal:

```asm
::
LOCALS

test1 PROC FAR
  MOV si,OFFSET Buffer
  CALL @@test2
::
```
The following code is not legal:

```
LOCALS
test1 PROC FAR
  MOV si,OFFSET Buffer
  CALL @@test2
  RET
test1 ENDP
```

since the CALL to @@test2 specifies a symbol local to the procedure test1, and no such symbol exists.

**Note** The `LOCALS` directive enables locally scoped symbols. See Chapter 11 for further information.

### Declaring method procedures for objects

Some special considerations apply when you create method procedures for objects. Object method procedures must be able to access the object that they are operating on, and thus require a pointer to that object as a parameter to the procedure.

Turbo Assembler’s treatment of objects is flexible enough to allow a wide range of conventions for passing arguments to method procedures. The conventions are constrained only by the need to interface with objects created by a high-level language.

If you are writing a native assembly-language object method procedure, you might want to use register argument passing conventions. In this case, you should write a method procedure to expect a pointer to the object in a register or register pair (such as ES:DI).
If you are writing a method procedure that uses high-level language interfacing conventions, your procedure should expect the object pointer to be one of the arguments passed to the procedure. The object pointer passed from high-level OOP languages like C++ is an implicit argument usually placed at the start of the list of arguments. A method procedure written in assembly language must include the object pointer explicitly in its list of arguments, or unexpected results will occur. Remember that the object pointer can be either a WORD or DWORD quantity, depending on whether the object is NEAR or FAR.

Other complexities arise when you write constructor or destructor procedures in assembly language. C++ uses other implicit arguments (under some circumstances) to indicate to the constructor or destructor that certain actions must be taken.

Constructors written for an application using native assembly language do not necessarily need a pointer to the object passed to them. If an object is never statically allocated, the object’s constructor will always allocate the object from the heap.

Note You can find information about the calling conventions of Borland C++ in Chapter 18.

Using procedure prototypes

For versions 3.2 and later, Turbo Assembler lets you declare procedure prototypes much like procedure prototypes in C. To do so, use the PROCDESC directive.

The Ideal mode syntax of PROCDESC is:

```
PROCDESC name [procedure_description]
```

Use the following syntax in MASM mode:

```
name PROCDESC [procedure_description]
```

`procedure_description` is similar to the language and argument specification used in the PROC directive. Its syntax is:

```
[[language_modifier] language] [distance] [argument_list]
```

`language_modifier`, `language`, and `distance` have the same syntax as in the PROC directive. `argument_list` has the form:

```
argument [,argument] ...
```

For more information about PROC, see the beginning of this chapter.

An individual argument has the following syntax:

```
[argument] [[count1_expression]]:complex_type [[count2_expression]]
```

`complex_type` is the data type of the argument, and can be either a simple type or a pointer expression. `count2_expression` specifies how many items of this type the argument defines. The default value of `count2_expression` is 1, except for arguments of BYTE, which have a default count of 2 (since you can’t PUSH a byte value onto the 80x86 stack). See Chapter 5 for further information about the syntax of complex types.
For the last argument, in procedure types whose calling convention allows variable-length arguments (like C), `count2_expression` can be `?`, to indicate that the procedure caller will determine the size of the array.

Note that the name of each argument (argname) is optional, but `complex_type` is required for each argument because procedure types are used mainly for type checking purposes. The names of the arguments do not have to agree, but the types must.

Here's an example:

```plaintext
  test PROCDESC pascal near a:word,b:dword,c:word
```

This example defines a prototype for the procedure `test` as a PASCAL procedure taking three arguments (WORD, DWORD, WORD). Argument names are ignored, and you can omit them in the `PROCDESC` directive, as follows:

```plaintext
  test PROCDESC pascal near :word,:dword,:word
```

The procedure prototype is used to check calls to the procedure, and to check the `PROC` declaration against the language, number of arguments, and argument types in the prototype. For example,

```plaintext
  test PROC pascal near
    ARG a1:word,a2:dword,a3:word ;matches PROCDESC for test
```

`PROCDESC` also globally publishes the name of the procedure. Procedures that are not defined in a module are published as externals, while procedures that are defined are published as public. Be sure that `PROCDESC` precedes the `PROC` declaration, and any use of the procedure name.

Procedure prototypes can also use procedure types (defined with `PROCTYPE`). For example,

```plaintext
  footype PROCTYPE pascal near :word,:dword,:word
  foo PROCDESC footype
```
Controlling the scope of symbols

In Turbo Assembler and most other programming languages, a symbol can have more than one meaning depending on where it’s located in a module. For example, some symbols have the same meaning across a whole module, while others are defined only within a specific procedure.

Symbol scope refers to the range of lines over which a symbol has a specific meaning. Proper scoping of symbols is very important for modular program development. By controlling the scope of a symbol, you can control its use. Also, properly selecting the scope of a symbol can eliminate problems that occur when you try to define more than one symbol of the same name.

Redefinable symbols

Some symbol types that Turbo Assembler supports are considered redefinable. This means that you can redefine a symbol of this type to be another symbol of the same type at any point in the module. For example, numeric symbols have this property:

```
foo = 1
mov ax,foo ;Moves 1 into AX.
foo = 2
mov ax,foo ;Moves 2 into AX.
```

Generally, the scope of a given redefinable symbol starts at the point of its definition, and proceeds to the point where it’s redefined. The scope of the last definition of the symbol is extended to include the beginning of the module up through the first definition of the symbol. For example,

```
mov ax,foo ;Moves 2 into AX!
foo = 1
mov ax,foo ;Moves 1 into AX.
foo = 2 ;This definition is carried around to the start
        ;of the module...
mov ax,foo ;Moves 2 into AX.
```
The following list contains the redefinable symbol types.

- text_macro
- numerical_expr
- multiline_macro
- struc/union
- table
- record
- enum

See Chapter 5 for more information about these redefinable symbols.

**Block scoping**

Block scoping makes a symbol have a scope that corresponds to a procedure in a module. Turbo Assembler supports two varieties of block scoping: MASM-style, and native Turbo Assembler style. By default, block-scoped symbols are disabled in Turbo Assembler.

**The LOCALS and NOLOCALS directives**

Turbo Assembler uses a two-character code prepended to symbols, which determines whether a symbol in a procedure has block scope. This local-symbol prefix is denoted with "@@." You can use the LOCALS directive to both enable block-scoped symbols, and to set the local symbol prefix. Its syntax looks like this:

```
LOCALS [prefix_symbol]
```

The optional `prefix_symbol` field contains the symbol (of two character length) that Turbo Assembler will use as the local-symbol prefix. For example,

```
LOCALS     ;@@ is assumed to be the prefix by default.
foo proc
@@a:      jmp @@a ;This @@a symbol belongs to procedure FOO.
foo endp

bar proc
@@a:      jmp @@a ;This @@a symbol belongs to procedure BAR.
bar endp
```

If you want to disable block-scoped symbols, you can use the NOLOCALS directive. Its syntax follows:

```
NOLOCALS
```

Note that you can also use block-scoped symbols outside procedures. In this case, the scope of a symbol is determined by the labels defined with the colon directive (:), which are not block-scoped symbols. For example,

```
foo:        ;Start of scope.
@@a:       ;Belongs to scope starting at FOO:
@@b = 1    ;Belongs to scope starting at FOO:
```
bar: ;Start of scope.
@@a = 2 ;Belongs to scope starting at BAR:

**MASM block scoping**

In MASM versions 5.1 and 5.2, NEAR labels defined with the colon directive (:) are considered block-scoped if they are located inside a procedure, and you’ve selected a language interfacing convention with the `MODEL` statement. However, these symbols are not truly block-scoped; they can’t be defined as anything other than a near label elsewhere in the program. For example,

```assembly
version m510
model small,c'
codeseg

foo proc
a: jmp a ;Belongs to procedure FOO
foo endp

bar proc
a: jmp a ;Belongs to procedure BAR
bar endp

a = 1; Illegal!
```

**MASM-style local labels**

MASM 5.1 and 5.2 provide special symbols that you can use to control the scope of near labels within a small range of lines. These symbols are: @@, @F, and @B.

When you declare @@ as a NEAR label using the colon (:) directive, you’re defining a unique symbol of the form @@xxxx (where xxxx is a hexadecimal number). @B refers to the last symbol defined in this way. @F refers to the next symbol with this kind of definition. For example,

```assembly
version m510
@@:
    jmp @B ;Goes to the previous @@.
    jmp @F ;Goes to the next @@.
@@:
    jmp @B ;Goes to the previous @@.
    jmp @F ;Error: no next @@.
```
Data allocation directives are used for allocating bytes in a segment. You can also use them for filling those bytes with initial data, and for defining data variables.

All data allocation directives have some features in common. First, they can generate initialized data and set aside room for uninitialized data. Initialized data is defined with some initial value; uninitialized data is defined without specifying an initial value (its initial value is said to be indeterminate). Data allocation directives indicate an uninitialized data value with a ?. Anything else should represent an initialized data value. Chapter 7 explains why you should distinguish between initialized and uninitialized data.

Another feature common to all data allocation directives is the use of the DUP keyword to indicate a repeated block of data. Here’s the general syntax of all data allocation directives:

```
[name] directive dup_expr [,dup_expr...]
```

Turbo Assembler initializes name to point to the space that the directive reserves. The variable will have a type depending on the actual directive used.

The syntax of each dup_expr can be one of the following:

- ?
- value
- count_expression DUP ( dup_expr[,dup_expr...] )

count_expression represents the number of times the data block will be repeated. count_expression cannot be relative or forward referenced.

Use the ? symbol if you want uninitialized data. The amount of space reserved for the uninitialized data depends on the actual directive used.

value stands for the particular description of an individual data element that is appropriate for each directive. For some directives, the value field can be very complex and contain many components; others may only require a simple expression. The following example uses the DW directive, which allocates WORDS:
Simple data directives

You can define data with the **DB**, **DW**, **DD**, **DQ**, **DF**, **DP**, or **DT** directives. These directives define different sizes of simple data, as shown in the following table.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB</strong></td>
<td>Define byte-size data.</td>
</tr>
<tr>
<td><strong>DW</strong></td>
<td>Define word-size data.</td>
</tr>
<tr>
<td><strong>DD</strong></td>
<td>Define doubleword-size data.</td>
</tr>
<tr>
<td><strong>DQ</strong></td>
<td>Define quadword-size data.</td>
</tr>
<tr>
<td><strong>DF</strong></td>
<td>Define 48-bit 80386 far-pointer-size (6 byte) data.</td>
</tr>
<tr>
<td><strong>DP</strong></td>
<td>Define 48-bit 80386 far-pointer-size (6 byte) data.</td>
</tr>
<tr>
<td><strong>DT</strong></td>
<td>Define tenbyte (10-byte) size data.</td>
</tr>
</tbody>
</table>

**Note**  
Data is always stored in memory low value before high value.

The syntax of the value field for each of these directive differs, based on the capability of each data size to represent certain quantities. (For example, it’s never appropriate to interpret byte data as a floating-point number.)

**DB** (byte) values can be

- A constant expression that has a value between −128 and 255 (signed bytes range from −128 to +127; unsigned byte values are from 0 to 255).
- An 8-bit relative expression using the HIGH or LOW operators.
- A character string of one or more characters, using standard quoted string format. In this case, multiple bytes are defined, one for each character in the string.

**DW** (word) values can be

- A constant expression that has a value between −32,768 and 65,535 (signed words range from −32,768 to 32,767; unsigned word values are from 0 to 65,535).
- A relative expression or address that requires 16 bits or fewer, (including an offset in a 16-bit segment, or a segment or group value).
- A one or two-byte string in standard quoted string format.

**DD** (doubleword) values can be

- A constant expression that has a value between −2,147,483,648 and 4,294,967,295 (when the 80386 is selected), or −32,768 and 65,535 otherwise.
- A relative expression or address that requires 32 bits or fewer (when the 80386 is selected), 16 bits or fewer for any other processor.
- A relative address expression consisting of a 16-bit segment and a 16-bit offset.
• A string of up to four bytes in length, using standard quoted string format.
• A short (32-bit) floating-point number.

DQ (quadword) values can be
• A constant expression that has a value between \(-2,147,483,648\) and \(4,294,967,295\)
  (when the 80386 is selected), or \(-32,768\) and \(65,535\) otherwise.
• A relative expression or address that requires 32 bits or fewer (when the 80386 is
  selected), or 16 bits or fewer for any other processor.
• A positive or negative constant that has a value between \(-2^{63}\) and \(2^{64}-1\)
  (signed quadwords range in value from \(-2^{63}\) to \(2^{63}-1\); unsigned quadwords have values from
  0 to \(2^{64}-1\)).
• A string of up to 8 bytes in length, using standard quoted string format.

• A long (64-bit) floating-point number.

DF, DP (80386 48-bit far pointer) values can be
• A constant expression that has a value between \(-2,147,483,648\) and \(4,294,967,295\)
  (when the 80386 is selected), or \(-32,768\) and \(65,535\) otherwise.
• A relative expression or address that requires 32 bits or fewer (when the 80386 is
  selected), or 16 bits or fewer for any other processor.
• A relative address expression consisting of a 16-bit segment and a 32-bit offset.
• A positive or negative constant that has a value between \(-2^{47}\) and \(2^{48}-1\)
  (signed 6-byte values range in value from \(-2^{47}\) to \(2^{47}-1\); unsigned 6-byte values have values from
  0 to \(2^{48}-1\)).
• A string of up to 6 bytes in length, in standard quoted string format.

DT values can be
• A constant expression that has a value between \(-2,147,483,648\) and \(4,294,967,295\)
  (when the 80386 is selected), or \(-32,768\) and \(65,535\) otherwise.
• A relative expression or address that requires 32 bits or fewer (when the 80386 is
  selected), or 16 bits or fewer for any other processor.
• A positive or negative constant that has a value between \(-2^{79}\) and \(2^{80}-1\)
  (signed tenbytes range in value from \(-2^{79}\) to \(2^{79}-1\); unsigned tenbytes have values from
  0 to \(2^{80}-1\)).
• A 10-byte temporary real formatted floating-point number.
• A string of up to 10 bytes in length, in standard quoted string format.
• A packed decimal constant that has a value between 0 and 99,999,999,999,999,999,999.

Numerical and string constants for the simple data allocation directives differ in some
cases from those found in standard Turbo Assembler expressions. For example, the DB,
DP, DQ, and DT directives accept quoted strings that are longer than those accepted
within an expression.
Quoted strings are delimited either by single quotes (' ) or double quotes ( " ). Inside of a string, two delimiters together indicate that the delimiter character should be part of the string. For example,

'what''s up doc?'

represents the following characters:

what's up doc?

You can have floating-point numbers as the value field for the DD, DQ, and DT directives. Here are some examples of floating-point numbers:

1.0E30 ; Stands for 1.0 x 10^30
2.56E-21 ; Stands for 2.56 x 10^-21
1.28E+5 ; Stands for 1.28 x 10^5
0.025 ; Stands for .025

Turbo Assembler recognizes these floating-point numbers because they contain a '.' after a leading digit. These rules are relaxed somewhat in MASM mode. For example,

DD 1E30 ; Legal MASM mode floating point value!
DD .123 ; Legal in MASM mode only.

Note For clarity, we recommend using the form with the leading digit and the decimal point.

Turbo Assembler also allows encoded real numbers for the DD, DQ, and DT directives. An encoded real number is a hexadecimal number of exactly a certain length. A suffix of R indicates that the number will be interpreted as an encoded real number. The length of the number must fill the required field (plus one digit if the leading digit is a zero); for example,

DD 12345678r ; Legal number
DD 012345678r ; Legal number
DD 1234567r ; Illegal number (too short)

The other suffix values ( D, H, O, Q, and B) function similarly to those found on numbers in normal expressions.

Some of the simple data allocation directives treat other numerical constant values specially. For example, if you don't specify radix for a value in the DT directive, Turbo Assembler uses binary coded decimal (BCD) encoding. The other directives assume a decimal value, as follows:

DD 1234 ; Decimal
DT 1234 ; BCD

The default radix (that the RADIX directive specifies) is not applied for the DD, DQ, and DT directives if a value is a simple positive or negative constant. For example,

RADIX 16
DW 1234 ; 1234 hexadecimal
DD 1234 ; 1234 decimal

Chapter 5 details numerical constants and the RADIX directive.
Creating an instance of a structure or union

To create an instance of a structure or a union data type, use the structure or union name as a data allocation directive. For example, assume you've defined the following:

```
ASTRUe
    B DB "xyz"
    C DW 1
    D DD 2
ASTRUe ENDS

BUNION UNION
    X DW ?
    Y DD ?
    Z DB ?
BUNION ends
```

Then the statements

```
ATEST ASTRUe
BTEST BUNION
```

would create instances of the structure `astruc` (defining the variable `atest`) and the union `bunion` (defining the variable `btest`). Since the example contained the `?` uninitialized data value, no initial data will be emitted to the current segment.

Initializing union or structure instances

Initialized structure instances are more complex than uninitialized instances. When you define a structure, you have to specify an initial default value for each of the structure members. (You can use the `?` keyword as the initial value, which indicates that no specific initial value should be saved.) When you create an instance of the structure, you can create it using the default values or overriding values. The simplest initialized instance of a structure contains just the initial data specified in the definition. For example,

```
ASTRUe {}
```

is equivalent to

```
DB "xyz"
DW 1
DD 2
```

The braces (`{ }`) represent a null initializer value for the structure. The initializer value determines what members (if any) have initial values that should be overridden, and by what new values, as you allocate data for the structure instance. The syntax of the brace initializer follows:

```
{ [member_name = value [,member_name = value...]] }
```

*member_name* is the name of a member of the structure or union. *value* is the value that you want the member to have in this instance. Specify a null value to tell Turbo Assembler to use the initial value of the member from the structure or union definition. A `?` value indicates that the member should be uninitialized. Turbo Assembler sets any
member that doesn’t appear in the initializer to the initial value of the member from the
structure or union definition. For example,

    ASTRU C (C=2,D=?)

is equivalent to

    DB "xyz"
    DW 2
    DD ?

You can use the brace initializer to specify the value of any structure or union member,
even in a nested structure or union.

Unions differ from structures because elements in a union overlap one another. Be
careful when you initialize a union instance since if several union members overlap,
Turbo Assembler only lets one of those members have an initialized value in an
instance. For example,

    BUNION {}

is valid because all three members of the union are uninitialized in the union definition.
This statement is equivalent to

    DB 4 DUP (?)

In this example, four bytes are reserved because the size of the union is the size of its
largest member (in this case a DWORD). If the initialized member of the union is not the
largest member of the union, Turbo Assembler makes up the difference by reserving
space but not emitting data. For example,

    BUNION (Z=1)

is equivalent to

    DB 1
    DB 3 DUP (?)

Finally, multiple initialized members in a union produce an error. For example, this is
illegal:

    BUNION (X=1,Z=2)

Note that if two or more fields of the union have initial values in the union definition,
then using the simple brace initializer ({ }) will also produce an error. The initializer
must set all but one value to ? for a legal instance to be generated.

An alternative method of initializing structure and union instances is to use the bracket
(<>) initializer. The values in the initializer are unnamed but are laid out in the same
order as the corresponding members in the structure or union definition. Use this syntax
for the bracket initializer:

    < [value [,value...]] >

value represents the desired value of the corresponding member in the structure or
union definition. A blank value indicates that you’ll use the initial value of the member
from the structure or union definition. A ? keyword indicates that the member should
be uninitialized. For example,
ASTRUC "abc",,?>
is equivalent to

DB "abc"
DW 1
DD ?

If you specify fewer values than there are members, Turbo Assembler finishes the instance by using the initial values from the structure or union definition for the remaining members.

ASTRUC "abc"> ;Same as ASTRUC "abc",,>

When you use the bracket initializer, give special consideration to nested structures and unions. The bracket initializer expects an additional matching pair of angle brackets for every level of nesting, so that Turbo Assembler will treat the nested structure or union initializer as a single entity (to match the value in the instance). Alternatively, you can skip an entire level of nesting by leaving the corresponding entry blank (for the default value of the nested structure or union), or by specifying the ? keyword (for an uninitialized nested structure or union). For example, examine the following nested structure and union:

CUNION
CTYPEDB ?
UNION; Start of union
 ;If CTYPE=0, use this...
STRUC
CT0PAR1 DW 1
CT0PAR2 DB 2
ENDS
 ;If CTYPE=1, use this...
STRUC
CT1PAR1 DB 3
CT1PAR2 DD 4
ENDS
ENDS; End of union
ENDS; End of structure data type

The bracket initializer for this complex structure/union has two levels of nesting. This nesting must appear as matched angle brackets within the initializer, like

CUNION <0,<<2>,?,>

This directive is equivalent to

DB 0
DW 2
DB 2
DB 2 DUP {?}
Creating an instance of a record

To create an instance of a record data type, use the name of the record data type as a data allocation directive. For example, assume you've defined the following:

```
MYREC RECORD VAL:3=4,MODE:2,SZE:4=15
```

Then, the statement

```
MTEST MYREC ?
```

would create an instance of the record `myrec` (defining the variable `mtest`). No initial data is emitted to the current segment in this example because the `?` uninitialized data value was specified.

Record instances are always either a byte, a word, or a doubleword, depending on the number of bits allocated in the record definition.

Initializing record instances

You must specify an initial value for some or all of the record fields when you define a record. (Turbo Assembler assumes that any unspecified initial values are 0.) The simplest initialized instance of a record contains just the initial field data specified in the definition. For example,

```
MYREC {}  
```

is equivalent to

```
DW (4 SHL 6) + (0 SHL 4) + (15 SHL 0)
```

;SHL is the shift left operator for expressions

The braces ({ }) represent a null initializer value for the record. The initializer value determines what initial values should be overridden, and by what new values (as you allocate data for the record instance).

Use this syntax of the brace initializer for records:

```
{ [field_name = expression [,field_name = expression...]] }
```

`field_name` is the name of a field in the record. `expression` is the value that you want the field to have in this instance. A blank value indicates that you'll use the initial value of the field from the record definition. A `?` value is equivalent to zero. Turbo Assembler sets any field that doesn't appear in the initializer to the initial value of the field from the record definition.

For example,

```
MYREC {VAL=2,SZE=?}
```

is equivalent to

```
DW (2 SHL 6) + (0 SHL 4) + (0 SHL 0)
```

An alternative method of initializing record instances is to use the bracket (`<>`) initializer. In this case, brackets delineate the initializer. The values in the initializer are unnamed but are laid out in the same order as the corresponding fields in the record definition. The syntax of the bracket initializer follows:

```
< [expression [,expression...]] >
```
expression represents the desired value of the corresponding field in the record definition. A blank value indicates that you'll use the initial value of the field from the record definition. A ? keyword indicates that the field should be zero. For example,

```
MYREC <,2,?>
```

is equivalent to

```
DW (4 SHL 6) + (2 SHL 4) + (0 SHL 0)
```

If you specify fewer values than there are fields, Turbo Assembler finishes the instance by using the initial values from the record definition for the remaining fields.

```
MYREC <1>; same as MYREC <1,>
```

Creating an instance of an enumerated data type

You can create an instance of an enumerated data type by using the name of the enumerated data type as a data allocation directive. For example, assume you have defined the following:

```
ETYPE ENUM FEE, FIE, FOO, FUM
```

Then the statement

```
ETEST ETYPE ?
```

would create an instance of the enumerated data type etype (defining the variable etest). In this example, no initial data is emitted to the current segment because the ? uninitialized data value is specified.

Enumerated data type instances are always either a byte, a word, or a doubleword, depending on the maximum value present in the enumerated data type definition.

Initializing enumerated data type instances

You can use any expression that evaluates to a number that will fit within the enumerated data type instance; for example,

```
ETYPE ? ; uninitialized instance
ETYPE FOO ; initialized instance, value FOO
ETYPE 255 ; a number outside the ENUM that also fits
```

Creating an instance of a table

To create an instance of a table data type, use the table name as a data allocation directive. For example, assume you have defined the following table:

```
TTYPE TABLE VIRTUAL DoneProc:WORD=DoneRtn,
   VIRTUAL MsgProc:DWORD=MsgRtn,
   VIRTUAL DoneProc:WORD=DoneRtn
```

Then, the statement

```
TTEST TTYPE ?
```
would create an instance of the table `tttype` (defining the variable `tttest`). No initial data will be emitted to the current segment in this example because the ? uninitialized data value was specified.

**Initializing table instances**

When you define a table, you must specify an initial value for all table members. The simplest initialized instance of a table contains just the initial data specified in the definition. For example,

```
TTTYPE {}  
```

is equivalent to

```
DW MoveRtn  
DD MsgRtn  
DW DoneRtn  
```

The braces (`{}`). represent a null initializer value for the structure. The initializer value determines what members (if any) have initial values that should be overridden, and by what new values, as you allocate data for the table instance.

Here's the syntax of the brace initializer:

```
{ [member_name = value [,member_name = value...]] }  
```

*member_name* is the name of a member of the table. *value* is the value that you want the member to have in this instance. A blank value indicates that you’ll use the initial value of the member from the table definition. A ? value indicates that the member should be uninitialized. Turbo Assembler sets any member that doesn’t appear in the initializer to the initial value of the member from the table definition. For example,

```
TTTYPE {MoveProc=MoveRtn2,DoneProc=?}  
```

is equivalent to

```
DW MoveRtn2  
DD MsgRtn  
DW ?  
```

**Creating and initializing a named-type instance**

You can create an instance of a named type by using the type name as a data allocation directive. For example, if you define the following type:

```
NTTYPE TYPEDEF PTR BYTE  
```

the statement

```
NTTEST NTTYPE ?  
```

creates an instance of the named type `nttype` (defining the variable `nttest`). No initial data is emitted to the current segment in this example because you specified the ? uninitialized data value.
The way that you initialize a named-type instance depends on the type that the named type represents. For example, NTTYPE in the previous example is a word, so it will be initialized as if you had used the DW directive, as follows:

```assembly
NTTYPE 1,2,3 ;Represents pointer values 1,2,3.
DW 1,2,3 ;Same as NTTYPE 1,2,3.
```

However, if the named type represents a structure or table, it must be initialized the same way as structures and tables are. For example,

```assembly
foo STRUC
f1 DB ?
ENDS
bar TYPEDEF foo
    bar {f1=1} ;Must use structure initializer.
```

Creating an instance of an object

Creating an instance of an object in an initialized or uninitialized data segment is exactly the same as creating an instance of a structure. In fact, objects in Turbo Assembler are structures, with some extensions. One of these extensions is the @Mptr_<object_name> structure member.

An object data type with virtual methods is a structure having one member that points to a table of virtual method pointers. The name of this member is @Mptr_<object_name>. Usually, you would initialize an instance of an object using a constructor method. However, you could have objects designed to be static and have no constructor, but are instead initialized with an initializer in a data segment.

If you use the @Mptr_<object_name> member’s default value, Turbo Assembler will correctly initialize the object instance.

Another difference between structures and objects is that objects can inherit members from previous object definitions. When this inheritance occurs, Turbo Assembler handles it as a nested structure. Because of this, we do not recommend using bracket (<>) initializers for object data.

Creating an instance of an object’s virtual method table

Every object that has virtual methods requires an instance of a table of virtual methods to be available somewhere. A number of factors determine the proper placement of this table, including what program model you’re using, whether you want near or far tables, and so forth. Turbo Assembler requires you to place this table. You can create an instance for the most recently defined object by using the TBLINST pseudo-op, with this syntax:

```
TBLINST
```

TBLINST defines @TableAddr_<object_name> as the address of the virtual table for the object. It is equivalent to

```assembly
@TableAddr_<object_name> @Table_<object_name> {}
```
Advanced coding instructions

Turbo Assembler recognizes all standard Intel instruction mnemonics applicable to the currently selected processor(s). You can find a detailed summary of these instructions in the quick reference guide. This chapter describes Turbo Assembler’s extensions to the instruction set, such as the extended CALL instruction for calling language procedures.

Intelligent code generation: SMART and NOSMART

Intelligent code generation means that Turbo Assembler can determine when you could have used different instructions more efficiently than those you supplied. For example, there are times when you could have replaced an LEA instruction by a shorter and faster MOV instruction, as follows:

LEA AX,lval

can be replaced with

MOV AX,OFFSET lval

Turbo Assembler supplies directives that let you use intelligent code generation. The following table lists these directives.

<table>
<thead>
<tr>
<th>Table 13.1 Intelligent code generation directives</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directive</td>
</tr>
<tr>
<td>SMART</td>
</tr>
<tr>
<td>NOSMART</td>
</tr>
</tbody>
</table>

By default, smart code generation is enabled. However, smart code generation is affected not only by the SMART and NOSMART directives, but also by the VERSION directive (see Chapter 3 for details on VERSION).

Smart code generation affects the following code generation situations:
• Replacement of LEA instructions with MOV instructions if the operand of the LEA instruction is a simple address.

• Generation of signed Boolean instructions, where possible. For example, AND AX,+02 vs. AND AX,0002.

• Replacement of CALL FAR xxxx with a combination of PUSH CS, CALL NEAR xxxx, when the target xxxx shares the same CS register.

Using *smart* instructions make it easier to write efficient code. Some standard Intel instructions have also been extended to increase their power and ease of use. These are discussed in the next few sections.

### Extended jumps

Conditional jumps such as JC or JE on the 80186, and 80286 processors are only allowed to be *near* (within a single segment) and have a maximum extent of -128 bytes to 127 bytes, relative to the current location counter. The same is true of the loop conditional instructions such as JCXZ or LOOP on all the Intel processors.

Turbo Assembler can generate complementary jump sequences where necessary and remove this restriction. For example, Turbo Assembler might convert

```
JC xxx
```

To

```
JNC temptag
JMP xxx
```

**Note** You can enable this complementary jump sequences with the **JUMPS** directive, and disable it with the **NOJUMPS** directive. By default, Turbo Assembler doesn’t generate this feature.

When you enable **JUMPS**, Turbo Assembler reserves enough space for all forward-referenced conditional jumps to a complementary jump sequence. When the actual distance of the forward jump is determined, you might not need a complementary sequence. When this happens, Turbo Assembler generates **NOP** instructions to fill the extra space.

To avoid generating extra **NOPs**, you can

• You can use an override for conditional jumps that you know are in range; for example,

```
JC SHORT abc
ADD ax,ax
abc:
```

• Specify the /m command-line switch. See Chapter 2 for more about this switch.
Additional 80386 LOOP instructions

The loop instructions for the 80386 processor can either use CX or ECX as the counting register. The standard LOOP, LOOPE, LOOPZ, LOOPNE, and LOOPNZ mnemonics from Intel select the counting register based on whether the current code segment is a 32-bit segment (when using ECX) or a 16-bit segment (when using CX).

Turbo Assembler has special instructions that increase the flexibility of the LOOP feature. The LOOPW, LOOPWE, LOOPWZ, LOOPWNE, and LOOPWNZ instructions use CX as the counting register, regardless of the size of the current segment. Similarly, the LOOPD, LOOPDE, LOOPDZ, LOOPDNE, and LOOPDNZ instructions use ECX as the counting register.

Additional 80386 ENTER and LEAVE instructions

Use the ENTER and LEAVE instructions for setting up and removing a procedure's frame on the stack. Depending on whether the current code segment is a 32-bit segment or a 16-bit segment, the standard ENTER and LEAVE instructions will modify either the EBP and ESP 32-bit registers, or the BP and SP 16-bit registers. These instructions might be inappropriate if the stack segment is a 32-bit segment and the code segment is a 16-bit segment, or the reverse.

Turbo Assembler provides four additional instructions that always select a particular stack frame size regardless of the code segment size. The ENTERW and LEAVEW instructions always use BP and SP as the stack frame registers, while the ENTERD and the LEAVED instructions always use EBP and ESP.

Additional return instructions

The standard RET instruction generates code that terminates the current procedure appropriately. This includes generating epilog code for a procedure that uses a high-level language interfacing convention. Even for a procedure with NOLANGUAGE as its calling convention, the RET instruction will generate different code if you declare the procedure NEAR or FAR. For a NEAR procedure, Turbo Assembler generates a near return instruction. For a FAR procedure, Turbo Assembler generates a far return instruction. (Outside of a procedure, a near return is always generated.)

Turbo Assembler contains additional instructions to allow specific return instructions to be generated (without epilog sequences). The following table lists them.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETN</td>
<td>Always generates a near return.</td>
</tr>
<tr>
<td>RETF</td>
<td>Always generates a far return.</td>
</tr>
<tr>
<td>RETCODE</td>
<td>Generates a return appropriate for the currently selected model. Generates a near return for models TINY, SMALL, COMPACT, and TPASCAL. Generates a far return for models MEDIUM, LARGE, HUGE, and TCHUGE.</td>
</tr>
</tbody>
</table>
Additional IRET instructions

For Turbo Assembler version 3.2 or later, you can use an expanded form of the IRET instruction. IRET will pop flags from the stack DWORD-style if the current code segment is 32-bit. Otherwise, a WORD-style POP is used. The IRETW instruction always pops WORD-style. Note that you can use these enhancements only if you select version T320. Otherwise, IRET will pop flags WORD-style, and IRETW is unavailable.

Extended PUSH and POP instructions

Turbo Assembler supports several extensions to the PUSH and POP instructions. These extensions greatly reduce the quantity of typing required to specify an extensive series of PUSH or POPs.

Multiple PUSH and POPs

You can specify more than one basic PUSH or POP instruction per line. For example,

PUSH ax
PUSH bx
PUSH cx
POP cx
POP bx
POP ax

can be written as

PUSH ax bx cx
POP cx bx ax

For Turbo Assembler to recognize there are multiple operands present, make sure that any operand cannot conceivably be considered part of an adjacent operand. For example,

PUSH foo [bx]

might produce unintended results because foo, [bx], and foo[ bx] are all legal expressions. You can use brackets or parentheses to clarify the instruction, as follows:

PUSH [foo] [bx]

Pointer PUSH and POPs

The standard PUSH and POP instructions can’t push far pointers, which require 4 bytes on the 8086, 80186, and 80286 processors, and up to 6 bytes on the 80386 processor.

Turbo Assembler permits PUSH and POP instructions to accept DWORD-sized pointer operands for the 8086, 80186, and 80286 processors, and PWORD and QWORD-sized pointer operands for the 80386 processor. When such a PUSH or POP is encountered, Turbo Assembler will generate code to PUSH or POP the operand into two pieces.
PUSHing constants on the 8086 processor

While the 80186, 80286, and 80386 processors have basic instructions available for directly PUSHing a constant value, the 8086 does not.

Turbo Assembler permits constants to be PUSHed on the 8086, and generates a sequence of instructions that has the exact same result as the PUSH of a constant on the 80186 and higher processors.

Note You can only do this if you’ve turned smart code generation on.

The sequence of instructions Turbo Assembler uses to perform the PUSH of a constant is about ten bytes long. There are shorter and faster ways of performing the same function, but they all involve the destruction of the contents of a register; for example,

```assembly
MOV ax, constant
PUSH ax
```

This sequence is only four bytes long, but the contents of the AX register is destroyed in the process.

Additional PUSHA, POPA, PUSHF and POPF instructions

For Turbo Assembler versions 3.2 or later, you can use an expanded form of the PUSHA, POPA, PUSHF and POPF instructions. If the current code segment is 32-bit, the PUSHA instruction will push registers in DWORD-style, and POPA will pop registers in DWORD-style. Otherwise, Turbo Assembler uses WORD-style PUSH and POP. Similarly, PUSHF and POPF will push and pop flags DWORD-style for a 32-bit code segment, or WORD-style otherwise.

The PUSHAW, POPAW, PUSHFW, and POPFW instructions always push and pop WORD-style. Remember that you can use these enhancements only if you’re using version T320 or later; otherwise, the pushes and pops will be done WORD-style.

The PUSHSTATE and POPSTATE instructions

The PUSHSTATE directive saves the current operating state on an internal stack that is 16 levels deep. PUSHSTATE is particularly useful if you have code inside a macro that functions independently of the current operating state, but does not affect the current operating mode.

The state information that Turbo Assembler saves consists of:

- Current emulation version (for example T310)
- Mode selection (for example IDEAL, MASM, QUIRKS, MASM51)
- EMUL or NOEMUL switches
- Current processor or coprocessor selection
- MULTErrS or NOMULTErrS switches
- SMART or NOSMARt switches
- The current radix
• JUMPS or NOJUMPS switches
• LOCALS or NOLOCALS switches
• The current local symbol prefix

Use the POPSTATE directive to return to the last saved state from the stack.

; PUSHSTATE and POPSTATE example

p286:
mov ax,1 ; Only AX available now. EAX would give errors.
cmp ax,1
jne next1 ; No extra NOPS after this
; Assemble with /la and check in .lst file.
mov ax,100 ; Now 100 means binary 100 or 4 decimal.
next1:
popstate ; Restores JUMPS and 386 mode and default radix.
cmp eax,4 ; EAX available again. Back in decimal mode.
je pass1 ; Extra NOPS to handle JUMPS. Check in .lst file
mov dx,OFFSET fail_string ; Load the fail string
jmp fini
pass1:
mov dx,OFFSET pass_string ; Load the pass string.
fini:
mov ax,@data ; Print the string out
mov ds,ax
mov ah,9h
int 21h
mov ah,4ch ; Return to DOS
int 21h
end
Extended shifts

On the 8086 processor, the shift instructions RCL, RCR, ROL, ROR, SHL, SHR, SAL, and SAR cannot accept a constant rotation count other than 1. The 80186, 80286, and 80386 processors accept constant rotation counts up to 255.

When Turbo Assembler encounters a shift instruction with a constant rotation count greater than 1 (with the 8086 processor selected), it generates an appropriate number of shift instructions with a rotation count of 1. For example,

```assembly
.8086
SHL ax, 4
```
generates

```assembly
SHL ax, 1
SHL ax, 1
SHL ax, 1
SHL ax, 1
```

Forced segment overrides: SEGxx instructions

Turbo Assembler provides six instructions that cause the generation of segment overrides. The following table lists these instructions.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEGCS</td>
<td>Generates a CS override prefix byte.</td>
</tr>
<tr>
<td>SEGSS</td>
<td>Generates an SS override prefix byte.</td>
</tr>
<tr>
<td>SEGDS</td>
<td>Generates a DS override prefix byte.</td>
</tr>
<tr>
<td>SEGES</td>
<td>Generates an ES override prefix byte.</td>
</tr>
<tr>
<td>SEGFS</td>
<td>Generates an FS override prefix byte.</td>
</tr>
<tr>
<td>SEGGS</td>
<td>Generates a GS override prefix byte.</td>
</tr>
</tbody>
</table>

You can use these instructions in conjunction with instructions such as XLATB, which do not require arguments, but can use a segment override. For example:

```assembly
SEGCS XLATB
```

Note that most such instructions have an alternative form, where you can provide a dummy argument to indicate that an override is required. For example,

```assembly
XLAT BYTE PTR cs:[bx]
```

These two examples generate exactly the same code.

Additional smart flag instructions

Often, you can simplify an instruction that manipulates bits in a flag to improve both code size and efficiency. For example,
might be simplified to

OR ah,10h

if the only result desired was to set a specific bit in AX, and the processor flags that the instruction affects are unimportant. Turbo Assembler provides four additional instructions that have this functionality, as shown in the following table:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Function</th>
<th>Corresponds to</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETFLAG</td>
<td>Set flag bit(s)</td>
<td>OR</td>
</tr>
<tr>
<td>MASKFLAG</td>
<td>Mask off flag bit(s)</td>
<td>AND</td>
</tr>
<tr>
<td>TESTFLAG</td>
<td>Test flag bit(s)</td>
<td>TEST</td>
</tr>
<tr>
<td>FLIPFLAG</td>
<td>Complement flag bit(s)</td>
<td>XOR</td>
</tr>
</tbody>
</table>

Use these instructions to enhance the modularity of records; for example,

P00   RECORD R0:1,R1:4,R2:3,R3:1
;
   TESTFLAG AX, MASK R0

In this example, TESTFLAG will generate the most efficient instruction regardless of where R0 exists in the record.

### Additional field value manipulation instructions

Turbo Assembler can generate specific code sequences for setting and retrieving values from bit fields specified with the RECORD statement. This lets you write code that is independent of the actual location of a field within a record. Used in conjunction with the ENUM statement, records can thus achieve an unprecedented level of modularity in assembly language. The following table lists these instructions:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETFIELD</td>
<td>Sets a value in a record field.</td>
</tr>
<tr>
<td>GETFIELD</td>
<td>Retrieves a value from a record field.</td>
</tr>
</tbody>
</table>

### The SETFIELD instruction

SETFIELD generates code that sets a value in a record field. Its syntax follows:

```plaintext
SETFIELD field_name destination_r/m, source_reg
```

field_name is the name of a record member field. destination_r/m for SETFIELD is a register or memory address of type BYTE or WORD (or DWORD for the 80386). source_reg must be a register of the same size or smaller. If the source is smaller than the destination, the source register must be the least significant part of another register that is the same size as the destination. This full-size register is called the operating register.
Use this register to shift the value in the source register so that it's aligned with the destination. For example,

```
FOO RECORD R0:1,R1:4,R2:3,R3:1
    
    SETFIELD R1 AX,BL  ; operating register is BX
    SETFIELD R1 AX,BH  ; illegal!
```

**SETFIELD** shifts the source register efficiently to align it with the field in the destination, and ORs the result into the destination register. Otherwise, **SETFIELD** modifies only the operating register and the processor flags.

**Note** Using **SETFIELD** will destroy the contents of the operating register.

To perform its function, **SETFIELD** generates an efficient but extended series of the following instructions: **XOR, XCHG, ROL, ROR, OR, and MOVZX.**

If you're using **SETFIELD** when your source and target registers are the same, the instruction does not OR the source value to itself. Instead, **SETFIELD** ensures that the fields of the target register not being set will be zero.

**SETFIELD** does not attempt to clear the target field before ORing the new value. If this is necessary, you must explicitly clear the field using the **MASKFLAG** instruction.

---

**The GETFIELD instruction**

**GETFIELD** retrieves data from a record field. It functions as the logical reverse of the **SETFIELD** instruction. Its syntax follows:

```
GETFIELD field_name destination_reg, source_r/m
```

*field_name* and *destination_reg* function as they do for **SETFIELD**. You can use *source_r/m* as you would for *source_reg* (for **SETFIELD**). For example,

```
FOO RECORD R0:1,R1:4,R2:3,R3:1
    
    GETFIELD R1 BL,AX  ; operating register is BX
    GETFIELD R1 BH,AX  ; illegal!
```

**Note** Note that **GETFIELD** destroys the entire contents of the operating register.

**GETFIELD** retrieves the value of a field found in the source register or memory address, and sets the pertinent portion of the destination register to that value. This instruction affects no other registers than the operating register and the processor flags.

To accomplish its function, **GETFIELD** generates an efficient but extended series of the following instructions: **MOV, XCHG, ROL, and ROR.**

If you're using the **GETFIELD** instruction when your source and target registers are the same, the instruction will not generate the nonfunctional **MOV target, source instruction.**
Additional fast immediate multiply instruction

Turbo Assembler provides a special immediate multiply operation for efficient array indexing. FASTIMUL addresses a typical problem that occurs when you create an array of structures. There is no immediate multiply operation available for the 8086 processor. Even for the more advanced processors, multiplication using shifts and adds is significantly faster in some circumstances than using the standard immediate IMUL instruction. Based on the currently specified processor, Turbo Assembler's FASTIMUL instruction chooses between the most efficient sequence of shifts and adds available, and the current processor's immediate IMUL operation (if any). FASTIMUL has the following syntax:

FASTIMUL dest_reg, source_r/m, value

This instruction is much like the trinary IMUL operation available on the 80186, 80286, and 80386 processors. The dest_reg destination register is a WORD register (or it can be DWORD on the 80386). source_r/m is a register or memory address that must match the size of the destination. value is a fixed, signed constant multiplicand.

FASTIMUL uses a combination of IMUL, MOV, NEG, SHL, ADD, and SUB instructions to perform its function. This function destroys the source register or memory address, and leaves the processor flags in an indeterminate state.

Extensions to necessary instructions for the 80386 processor

The 80386 processor has the ability to operate in both 16-bit and 32-bit mode. Many of the standard instructions have different meanings in these two modes. In Turbo Assembler, you can control the operating size of the instruction using the SMALL and LARGE overrides in expressions.

In general, when you use SMALL or LARGE as part of an address expression, the operator controls the generation of the address portion of the instruction, determining whether it should be 16- or 32-bit.

When SMALL or LARGE appears outside of the address portion of an expression, it can control whether a 16-bit instruction or a 32-bit instruction is performed. In cases where you can determine the size of the instruction from the type of the operand, Turbo Assembler selects the size of the instruction. The following table shows the instructions that SMALL and LARGE affect.

Table 13.6 Instructions affected by SMALL and LARGE

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>PUSH [SMALL/LARGE] segreg</td>
<td>Selects whether 16-bit or 32-bit form of segment register is PUSHed.</td>
</tr>
<tr>
<td>POP [SMALL/LARGE] segreg</td>
<td>Selects whether 16-bit or 32-bit form of segment register is POPped.</td>
</tr>
<tr>
<td>FSAVE [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of floating-point state is saved.</td>
</tr>
<tr>
<td>FRSTOR [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of floating-point state is restored.</td>
</tr>
<tr>
<td>FSTENV [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of floating-point state is stored.</td>
</tr>
<tr>
<td>FLDENV [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of floating-point state is loaded.</td>
</tr>
<tr>
<td>LGDT [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of global descriptor table is loaded.</td>
</tr>
</tbody>
</table>
Table 13.6  Instructions affected by SMALL and LARGE (continued)

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>SGDT [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of global descriptor table is saved.</td>
</tr>
<tr>
<td>LIDT [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of interrupt descriptor table is loaded.</td>
</tr>
<tr>
<td>SIDT [SMALL/LARGE] memptr</td>
<td>Selects whether small or large version of interrupt descriptor table is saved.</td>
</tr>
<tr>
<td>JMP [SMALL/LARGE] memptr</td>
<td>For DWORD-sized memory addresses, selects between FAR 16-bit JMP and NEAR 32-bit JMP.</td>
</tr>
<tr>
<td>CALL [SMALL/LARGE] memptr</td>
<td>For DWORD-sized memory addresses, selects between FAR 16-bit CALL and NEAR 32-bit CALL.</td>
</tr>
</tbody>
</table>

Note  Turbo Assembler selects the size of the instruction using SMALL and LARGE only when no other information is available. For further information about overriding address sizes with the SMALL and LARGE operators, see Chapter 5.

Calling procedures with stack frames

Turbo Assembler supports an extended form of the CALL instruction that lets you directly call procedures that use high-level language interfacing conventions.

Arguments to procedures that use high-level language interfacing conventions are passed on the stack in a stack frame. The caller must push these arguments onto the stack before calling the procedure.

The interfacing convention of the procedure determines the order arguments should be pushed into the stack frame. For BASIC, FORTRAN, and PASCAL procedures, arguments are pushed onto the stack in the order they are encountered; for C and CPP (C++), the arguments are pushed in the reverse order.

The interfacing convention of a procedure also determines whether the procedure or the caller of the procedure must remove the arguments from the stack once the procedure is called. C and C++ require the caller to clean up the stack. In all other languages, the procedure itself must remove the arguments from the stack before returning.

Turbo Assembler handles both the proper argument ordering and stack cleanup for you with the extended CALL instruction. The syntax for calling a procedure with parameters follows:

```
CALL expression [language] [,argument_list]
```

`expression` is the target of the CALL instruction. `language` specifies the interfacing convention to use for the call. If you don’t specify a language, Turbo Assembler uses the default language set by MODEL (see Chapter 7 for further information about using MODEL).

Arguments, if any, follow the language identifier. The syntax of each argument in the argument list is the same as for the extended PUSH and POP instructions. You can separate these arguments with commas; for example,

```
CALL test PASCAL,ax,es OFFSET buffer,blen
```

PASCAL, the language in the example, causes Turbo Assembler to push the arguments in the same order that it encounters them. This example call is equivalent to
A call to a C procedure requires that the arguments be pushed onto the stack in the reverse order. Turbo Assembler automatically does this so that a call of the form

```
CALL test C,ax,es OFFSET buffer,word PTR bIen
```

results in the following code:

```
PUSH word PTR bIen
PUSH es OFFSET buffer
PUSH ax
CALL test
SUB sp,8
```

When calling a procedure with arguments, you should always list the arguments in the same order they were listed in the procedure header. Turbo Assembler reverses them if necessary.

**Note** Remember to separate arguments with commas and components of arguments with spaces. Turbo Assembler, depending on the interfacing convention, can push arguments in reverse order on the stack, but it won’t alter the ordering of argument components.

If the interfacing convention for the call is NOLANGUAGE, Turbo Assembler reports an error if any arguments are present. Although you can define arguments to a NOLANGUAGE procedure with the ARG directive, you must explicitly push the arguments when you make a call to a NOLANGUAGE procedure.

### Calling procedures that contain RETURNS

Procedures that define some of their arguments with the RETURNS keyword must be considered specially. These arguments are used to return values to the caller; therefore, the caller always pops them. There is no special extension to the CALL instruction in Turbo Assembler to help pass those arguments specified in a procedure declaration after the RETURNS directive. You must explicitly PUSH these arguments before the CALL, and POP them afterward.

### Calling procedures that have been prototyped

If you’ve defined the procedure prior to the call or used PROCDESC to prototype the procedure (see Chapter 10), Turbo Assembler will type check any language and arguments specified in the call and generate a warning if the language, number of parameters, or types of parameters don’t match.

For example,
test PROCDESC pascal far :word,:dword,:word
    ;
call test pascal ax,ds bx,cx ;works fine
call test c, ax, dx, bx, cx ; wrong language!
call test pascal, eax, ebx, ecx ; wrong parameter types!
call test pascal, ax, ds bx ; too few parameters!

Since the language of the procedure has been specified, you don't have to include it in the call. If you omit it, however, make sure to include the comma that would normally follow it:

call test, ax, ds bx, cx ; works fine

You can also use procedure types (declared with PROCTYPE) to supply a distance and language, and force type-checking to occur. For example,

footype proctype pascal near :word,:dword,:word
    ;
call footype ptr[bx], ax, ds bx, cs ; no error!

**Calling method procedures for objects: CALL..METHOD**

The CALL instruction is extended to support the calling of object methods. A call to an object method can generate either a direct call (for static methods) or an indirect call (for virtual methods).

Because you can use an indirect call, the instructions that perform the call can destroy the contents of some registers. Therefore, Turbo Assembler lets you select the proper registers if you're using a virtual method call.

Here's the syntax of the CALL..METHOD extension:

```
CALL instance_ptr METHOD [object_name:]method_name [USES [segreg:]offsreg] [language_and_args]
```

*instance_ptr* must describe an instance of an object. In MASM mode, it's often impossible to determine the name of the object associated with an instance. Therefore, Turbo Assembler allows the *object_name* field, so that you can specify the instance's object name.

*method_name* contains the name of the method to be called for the specified object instance.

See Chapter 8 for further information about how to specify a method as virtual or static.

If the method is virtual and an indirect call is required, the CALL..METHOD instruction normally calls indirectly through ES:BX (or ES:EBX for USE32 models on the 80386 processor). If you want to use other registers, you can override them with the USES clause. *segreg* is the optional segment register to use, and *offsreg* is the offset register to use for the call.

For objects declared with near tables, CALL..METHOD only loads the offset register. Turbo Assembler assumes that the segment register is already set up to the correct value.
Note  It’s good programming practice to specify an appropriate selection for indirect calling registers, even if you know that the method you’re calling is static. As objects are modified, methods can change from being static to virtual.

The language_and_args field of the CALL..METHOD instruction contains the optional language and argument specifications, which are identical in form to that listed previously under “Calling procedures with stack frames.”

 Calling method procedures for C++ or Pascal usually requires that the instance of the object be passed as an argument on the stack. See Chapter 18 for further information.

Tail recursion for object methods: JMP..METHOD

Turbo Assembler provides a JMP..METHOD instruction that corresponds to the CALL..METHOD instruction. Here’s its syntax:

```
JMP instance_ptr METHOD [object_name:]method_name [USES [segreg:]offsreg]
```

JMP..METHOD functions exactly like CALL..METHOD except that

- It generates a JMP instead of a CALL instruction.
- It generates procedure epilog code to clean up the stack before the JMP instruction is generated.

The JMP..METHOD instruction makes it possible to write efficient tail recursion code. It’s intended to replace the common situation where a CALL..METHOD instruction is issued to the current method, followed by a RET instruction.

Additional instruction for object-oriented programming

When an object instance is constructed, you must initialize the instance’s virtual table pointer (if any) to point to the correct virtual method table. The TBLINIT instruction lets you do this automatically. The syntax of the TBLINIT instruction is

```
TBLINIT object_instance_pointer
```

The object_instance_pointer field is the address of the object whose virtual table pointer is to be initialized. The TBLINIT instruction assumes that the object instance should be of the current object type (in other words, the immediately preceding object definition determines the object type that TBLINIT initializes). For example,

```
TBLINIT DS:SI
```

would initialize the virtual table pointer of the object at DS:SI, if it has one.
Using macros

Macros let you give a symbolic name to a text string or a block of code that will be used frequently throughout your program. Macros go beyond this simple substitution, however. Turbo Assembler has macro operators that provide great flexibility in designing macros. Combined with the ability to use multiline macros with arguments, this makes Turbo Assembler’s macro facility a very powerful tool. This chapter discusses how to use text and multiline macros in your program.

Text macros

A text macro is a symbol that represents a string of text characters. When Turbo Assembler encounters the symbol in expressions (and other situations), it substitutes the text characters for the symbol. For example, if DoneMsg is a text macro whose value is “Returning to the OS”, the following statement

```assembly
GoodBye DB DoneMsg
```

results in

```assembly
GoodBye DB 'Returning to the OS'
```

**Defining text macros with the EQU directive**

You can use the EQU directive to define simple text macros. Here’s the syntax for defining a text macro:

```assembly
name EQU text_string
```

`text_string` associates with the text macro name `name`. You should enclose `text_string` in brackets (<> ) to delineate the text; for example,

```assembly
DoneMsg   EQU '<Returning to the OS'>
```

**Note** If you omit the brackets in MASM mode, Turbo Assembler will try to evaluate `text_string` to an expression, and an error may result. Only if it can’t evaluate `text_string`
will Turbo Assembler treat it as a text macro (to remain compatible with MASM). In Ideal mode, EQU always defines a text macro. If you don’t enclose \textit{text_string} in brackets and it’s the name of another text macro, Turbo Assembler will use that macro’s contents. Otherwise, the macro will be defined to the text.

You should always enclose text macro strings in angle brackets to make sure they’re properly defined. Consider the following mistake that can occur when you don’t:

\begin{verbatim}
IDEAL
Earth EQU dirt ;Earth = "dirt"
Planet EQU Earth ;Planet = "dirt" (wrong!)
Planet EQU <Earth> ;Planet = "Earth" (correct!)
\end{verbatim}

In Ideal mode, the \texttt{EQU} statement always defines a text macro.

Text macros are redefinable; you can redefine a text macro name in the same module to another text string.

**String macro manipulation directives**

Turbo Assembler provides directives that can manipulate string macros. These directives are available in Ideal mode, and for versions M510, M520, and T300 or later (as specified by the \texttt{VERSION} directive).

A \textit{string} argument for any of these directives can be any of the following:

- a text string enclosed in brackets; for instance, \texttt{<abc>}
- the name of a previously defined text macro
- an expression preceded by a \% character, whose value is converted to the equivalent numerical string representation appropriate for the current radix

**The CATSTR directive**

The \texttt{CATSTR} directive defines a new text macro by concatenating strings together. \texttt{CATSTR} has the following syntax:

\begin{verbatim}
name CATSTR string[,string] ...
\end{verbatim}

\texttt{CATSTR} concatenates from left to right. Turbo Assembler creates a new text macro of the name \texttt{name}.

**The SUBSTR directive**

The \texttt{SUBSTR} directive defines a new text macro to be a substring of a string. Here’s its syntax:

\begin{verbatim}
name SUBSTR string,position_expression[,size_expression]
\end{verbatim}

The new text macro, \texttt{name} consists of the portion of \texttt{string} that starts at the \texttt{position_expression} character, and is \texttt{size_expression} characters in length. If you don’t supply \texttt{size_expression}, the new text macro consists of the rest of \texttt{string} from the character at \texttt{position_expression}. Turbo Assembler considers the first character of \texttt{string} to be at position 1.
The **INSTR** directive

The **INSTR** directive returns the position of one string inside another string. **INSTR** has the following syntax:

```
name INSTR [start_expression] string1,string2
```

Turbo Assembler assigns `name` a numeric value that is the position of the first instance of `string2` in `string1`. The first character in `string1` has a position of 1. If `string2` does not appear anywhere within `string1`, Turbo Assembler returns a value of 0. If you include `start_expression`, the search begins at the `start_expression` character. The first character of a string is 1.

The **SIZESTR** directive

The **SIZESTR** directive returns the length of a text macro (the number of characters in the string). Here’s its syntax:

```
name SIZESTR string
```

`name` is set to the numeric value of the length of the `string`. A null string `< >` has a length of zero.

**Text macro manipulation examples**

The following examples show how these operators work:

```assembly
VERSION T300
IDBAL
ABC EQU <abc> ; ABC = "abc"
ABC2 EQU ABC ; ABC2 = "abc"
ABC EQU <def> ; ABC = "def" (redefined)
ABC3 CATSTR ABC2,<>,ABC,<>,ABC2 ; ABC3 = "abc,def,abc"
ABCLEN SIZESTR ABC ; ABCLEN = 3
ABC3LEN SIZESTR ABC3 ; ABC3LEN = 11
COMMA1 INSTR ABC3,<> ; COMMA1 = 4
COMMA2 INSTR COMMA1+1,ABC3,<> ; COMMA2 = 8
ABC4 SUBSTR ABC3,5 ; ABC4 = "def,abc"
ABC5 SUBSTR ABC3,5,3 ; ABC5 = "def"
ABC6 EQU 3+2+1 ; ABC6 = 6 (numeric equate)
ABC7 EQU %3+2+1 ; ABC7 = "6" (text macro)
ABC8 EQU %COMMA1 ; ABC8 = "4"
```

**Multiline macros**

The multiline macro facility lets you define a body of instructions, directives, or other macros that you’ll include in your source code whenever the macro is invoked. You can supply arguments to the macro that Turbo Assembler will substitute into the macro body when you include the macro in the module.

There are several types of multiline macros. One version substitutes each element of a string, one after the other, as an argument to the macro. Another version repeats the macro body a certain number of times. Finally, you can define still another version in
one place, and invoke it many times. All versions have the definition of a macro body in common.

**The multiline macro body**

Regardless of its actual content, Turbo Assembler's macro processing facility treats a multiline macro body as merely a number of lines of text. Turbo Assembler lets you replace symbols within the macro body with text specified at the time a macro is invoked. This feature is called *argument substitution*. The symbols in the macro body that will be replaced are called *dummy arguments*. For example, suppose the symbol `foo` is a dummy argument in the following macro body:

```asm
PUSH foo
MOV foo,1
```

If you assign `foo` with the text string `AX` when you invoke this macro, the actual text included in the module will be:

```asm
PUSH AX
MOV AX,1
```

The rules Turbo Assembler uses for recognizing a dummy argument are fairly complex. Examine the following macro body lines where the dummy argument `foo` would not be recognized:

```asm
symfoo:
  DB 'It is foo time'
```

In general, Turbo Assembler will not recognize a dummy argument without special help in the following situations:

- when it is part of another symbol
- when it is inside of quotation marks (` or `)
- in Ideal mode, when it appears after a semicolon not inside of quotes

**Using & in macros**

The `&` character has a special meaning when used with the macro parameters. In general, `&` separates a dummy argument name from surrounding text, so Turbo Assembler can recognize it for substitution. For example, given the following Ideal mode macro:

```asm
macro macl foo
  sym&foo:
    DB 'It is &foo time'
  endm
```

if you assign `foo` the text string `party` when this macro is invoked, the actual text included in the module will be:

```asm
symparty:
  DB 'It is party time'
```

Another example might be:

```asm
foo&sym:
```
If you assign \textit{foo} the text string \textit{hi} when this macro is invoked, the text included in the module will be

\begin{verbatim}
hisym:
DB 'We are in Ohio'
\end{verbatim}

\textbf{Note} Here are the rules for the \& character:

\begin{itemize}
  \item Outside quoted strings, the \& serves only as a general separator.
  \item Inside quoted strings and after a semicolon that's not in a quoted string in Ideal mode, \& must precede a dummy argument for it to be recognized.
  \item Turbo Assembler removes one \& from any group of \&s during a macro expansion.
\end{itemize}

The last point makes it possible to place macro definitions requiring \& characters inside other macro definitions. Turbo Assembler will remove only one \& from any group.

\section*{Including comments in macro bodies}

For particularly complicated macros, you might want to include (in the macro body text) comments that won't be included when the macro is invoked. This also reduces the memory required for Turbo Assembler to process macros. To do this, use the double semicolon comment at the beginning of a line. For example, the following macro body

\begin{verbatim}
;;Wow, this is a nasty macro!
DB 'Nasty macro'
\end{verbatim}

will only include the following text when it is invoked:

\begin{verbatim}
DB 'Nasty macro'
\end{verbatim}

\textbf{Note} Comments preceded by single semicolons are always included in a macro expansion.

\section*{Local dummy arguments}

At the beginning of any macro body, you can include one or more \texttt{LOCAL} directives. \texttt{LOCAL} declares special dummy arguments that, each time the macro expands, will be assigned a unique symbol name.

The syntax for the \texttt{LOCAL} directive in macro bodies looks like this:

\begin{verbatim}
LOCAL dummy_argument1 [,dummy_argument2]...
\end{verbatim}

When using this syntax, note that the \texttt{LOCAL} directive must come before any other statements in a macro body.

If the \textit{dummy_argument} name used in the \texttt{LOCAL} directive does not have a local symbol prefix the unique symbol name assigned to it will be in the form \texttt{??xxxx}, where \texttt{xxxx} represents a hexadecimal number. Otherwise, the unique symbol name will be \texttt{<local prefix>xxxx}. For details on how to enable local symbols and set the local symbol prefix, see Chapter 11.

You can use \texttt{LOCAL} dummy arguments to define labels within the macro body. For example,
LOCAL @@agn, @@zero
XOR dx,dx
MOV cx,exp
MOV ax,1
JCXZ @@zero
MOV bx,factor
@@agn: MUL bx
LOOP @@agn
@@zero:

Note In macros, you don’t have to use @@ since local labels in macros are turned into consecutive numbers, like ??0001. Their names are not easily accessible outside macros.

The EXITM directive
You can use the EXITM directive within a macro body to prematurely terminate the assembly of an included macro body. Its syntax follows:

EXITM

When Turbo Assembler encounters EXITM in a macro body that has been included in the module source code, assembly of the expanded macro body stops immediately. Instead, Turbo Assembler will continue assembling the module at the end of the macro.

You can use the EXITM statement with a conditional assembly directive to terminate a macro expansion when certain conditions are met.

Tags and the GOTO directive
Using macro tags and the GOTO directive lets you control the sequence in which lines within the macro body expand. You can place a macro tag at any place within the macro body. The tag occupies an entire line in the macro, with the following syntax:

: tag_symbol

When the macro expands, all macro tags are discarded.

The GOTO directive tells the assembler to go to a specified point in your code, namely the tag_symbol. GOTO has the following syntax:

GOTO tag_symbol

GOTO also terminates any conditional block that contains another GOTO. This lets you place GOTO inside conditional assembly blocks. For example,

IF foo
  GOTO tag1
ENDIF
  DISPLAY 'foo was false!'
:tag1
  ;resume macro here...
  ;works the same whether foo was false or true

Note Be careful not to create infinite macro loops when you use the GOTO directive. Infinite loops can cause Turbo Assembler to run out of memory, or even appear to stop functioning.
See Chapter 15 for further information about conditional assembly directives.

**General multiline macros**

Turbo Assembler associates a general multiline macro’s body of directives, instructions, and other macros with a symbolic macro name. Turbo Assembler inserts the body of statements into your program wherever you use the macro name as a directive. In this way, you can use a general multiline macro more than once.

**Note**

You can invoke a macro before you define it only when you use the `/m` command-line switch as explained in Chapter 2. However, this is considered to be poor programming practice.

Here’s the Ideal mode syntax for defining a general multiline macro:

```assembly
MACRO name parameter_list
    macro_body
ENDM
```

Here’s the MASM mode syntax for defining a general multiline macro:

```assembly
name MACRO parameter_list
    macro_body
ENDM
```

`name` is the name of the multiline macro you’re defining, `macro_body` contains the statements that make up the body of the macro expansion. You can place any valid (and any number of) Turbo Assembler statements within a macro. The `ENDM` keyword terminates the macro body.

This example defines a macro named `PUSHALL` that, when invoked, includes the macro body consisting of three `PUSH` instructions into your program.

```assembly
PUSHALL MACRO
    PUSH AX BX CX DX
    PUSH DS SI
    PUSH ES DI
ENDM
```

`parameter_list` is a list of dummy argument symbols for the macro. Here’s its syntax:

```
[dummy_argument [,dummy_argument ...]]
```

You can use any number of dummy arguments with a macro, as long as they fit on one line, or you use the line continuation character (`\`) to continue them to the next line. For example,

```assembly
ADDUP MACRO dest,\ ;dest is 1st dummy argument
       s1,s2 ;s1,s2 are 2nd and 3rd dummy arguments
    MOV dest,s1
    ADD dest,s2
ENDM
```

Each dummy argument has the following syntax:

```
dummy_name[:dummy_type]
```
dummy_name is a symbolic name used as a place holder for the actual argument passed to the macro when it's invoked. The optional dummy_type specifies something about the form the actual argument must take when you invoke the macro. The following types are supported:

Table 14.1 Dummy argument types

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>REQ</td>
<td>Argument cannot be null or spaces.</td>
</tr>
<tr>
<td>&lt;text_string&gt;</td>
<td>Bracketed text string is the default value for the dummy argument when the actual argument is null or contains spaces.</td>
</tr>
<tr>
<td>VARARG</td>
<td>Actual argument consists of the rest of the macro invocation, interpreted as a list of arguments. Commas and angle brackets are added to ensure this interpretation.</td>
</tr>
<tr>
<td>REST</td>
<td>Actual argument consists of the rest of the macro invocation, interpreted as raw text.</td>
</tr>
</tbody>
</table>

Invoking a general multiline macro

To invoke a general multiline macro, use the name of the macro as a directive in your program. Turbo Assembler inserts the macro body (after all the dummy arguments are substituted) at that point in the module. The syntax for invoking a general multiline macro is as follows:

```
macro_name [argument [[,]argument]...]
```

macro_name is the symbolic name of a macro. If you invoke a macro with arguments, the arguments are listed following the macro name. You can specify any number of arguments, but they must all fit on one line. Separate multiple arguments with commas or spaces. When the macro expands, Turbo Assembler replaces the first dummy argument in the macro definition with the first argument passed, the second dummy argument with the second argument, and so forth.

Each argument represents a text string. You can specify this text string in the following ways:

- as a contiguous group of characters, not containing any whitespace, commas, or semicolons
- as a group of characters delineated by angle brackets (< >), which can contain spaces, commas, and semicolons
- as a single character preceded by a ! character, which is equivalent to enclosing the character in angle brackets
- as an expression preceded by a % character, which represents the text value of the expression appropriate for the currently selected radix

The < > literal string brackets

Use angle brackets to delineate a literal string that contains the characters between them. You should use them like this:

```
<text>
```
text is treated as a single string parameter, even if it contains commas, spaces, or tabs that usually separate each parameter. Use this operator when you want to pass an argument that contains any of these separator characters.

You can also use this operator to force Turbo Assembler to treat a character literally, without giving it any special meaning. For example, if you want to pass a semicolon (;) as a parameter to a macro invocation, you have to enclose it in angle brackets (<;>) to prevent it from being treated as the beginning of a comment. Turbo Assembler removes only one level of angle brackets when it converts a bracketed string to a text argument. This makes it possible to invoke a macro requiring angle brackets from inside another macro body.

The ! character
The ! character lets you invoke macros with arguments that contain special characters. Using this character prior to another is similar to enclosing the second character in angle brackets. For example, !; functions the same as <;>. Some common uses are shown in the following table.

<table>
<thead>
<tr>
<th>String</th>
<th>Resulting character</th>
</tr>
</thead>
<tbody>
<tr>
<td>!&gt;</td>
<td>&gt;</td>
</tr>
<tr>
<td>!&lt;</td>
<td>&lt;</td>
</tr>
<tr>
<td>!!</td>
<td>!</td>
</tr>
</tbody>
</table>

The % expression evaluation character
The % character causes Turbo Assembler to evaluate an expression. The assembler converts the result of the expression to an ASCII number in the current radix, which is the text that the % character produces. Use this character when you want to pass the string representing a calculated result, rather than the expression itself, as a macro argument. The syntax follows:

%expr

expr can be either an expression (using any legal operands and operators), or it can be the name of a text macro. If it is an expression, the text that is produced is the result of the expression, represented as a numerical string in the current radix. If expr is a text macro name, the text that's produced is the string that the text macro represents. See Chapter 5 for more information about Turbo Assembler expressions.

For example, this code

```assembly
DEFSYM MACRO NUM
TMP_&NUM:
ENDM
TNAME EQU <JUNK> ;defining a text macro
DEFSYM &5+4
DEFSYM &TNAME
```
results in the following code macro expansions:

```
TMP_9:
TMP_JUNK:
```

**Redefining a general multiline macro**
You can redefine general multiline macros. The new definition automatically replaces the old definition. All preceding places where the macro had already been invoked will not change. All invocations of the macro following the redefinition use the new definition.

**Deleting a general multiline macro: The PURGE directive**
You can use the PURGE directive to delete a macro. PURGE has the following syntax:

```
PURGE macroname [,macroname]...
```

**PURGE** deletes the general multiline macro definition associated with *macroname*. After you **PURGE** a macro, Turbo Assembler no longer treats the symbol *macroname* as if it were a macro; for example,

```
ADD MACRO a1,a2
SUB a1,a2
ENDM
ADD ax,bx  ;This invocation will produce SUB ax,bx
PURGE ADD
ADD ax,bx  ;This is no longer a macro, so ADD ax,bx is produced
```

You can purge several macros at a time by separating their names with commas. Note, however, that you can’t redefine a purged macro symbol as anything other than another macro.

**Defining nested and recursive macros**
The statements in a macro body can include statements that invoke or define other macros. If you take this example,

```
MCREATE MACRO opname,op1,op2,op3,op4,op5,op6,op7
IFNB opname
DO&opname MACRO op,count
   IF count LE 4
      REPT count 
         opname op,l
      ENDM
   ELSE
      MOV CL,count
      opname op,CL
   ENDIF
 ENDIF
ENDM ;end of DOopname macro
MCREATE op1,op2,op3,op4,op5,op6,op7 ;recurse!
ENDM ;end of if
ENDM ;end of MCREATE macro
```
and invoke it with

\texttt{MCREATE \textit{ror,rol,rcl,rcr,shl,shr,sal,sar}}

it will create the additional macros \texttt{DOror, DOrol}, and so forth, which you can then use like this:

\begin{verbatim}
DOshr  ax,5
DOrcr  bx,3
\end{verbatim}

You can call recursive macros with a list of parameters, and set them up so that the macro will work with anywhere from zero to a maximum number of parameters. To do this, have the macro body use the first parameter to do its expansion, then call itself with the remaining parameters. Every time it recurses, there will be one fewer parameter. Eventually, it will recurse with no parameters.

When you call the macro recursively, it always needs some way to test for the end of the recursion. Usually, an \texttt{IFNB} conditional statement will do this for only the macro body if the passed parameter is present. Here is a simpler example of a recursive macro:

\begin{verbatim}
PUSHM MACRO r1,r2,r3,r4,r5,r6,r7,r8
  IFNB r1
    push r1
    PUSHM r2,r3,r4,r5,r6,r7,r8
  ENDIF
ENDM
\end{verbatim}

\textbf{Note} See Chapter 15 for more information about the \texttt{IFNB} directive.

\section*{The count repeat macro}

You can use the \texttt{REPT} repeating macro directive to repeat a macro body a specific number of times, using this syntax:

\begin{verbatim}
  \texttt{REPT} expression
  \texttt{macro_body}
  \texttt{ENDM}
\end{verbatim}

\textit{expression} tells Turbo Assembler how many times to repeat the macro body specified between the \texttt{REPT} and \texttt{END} directives. \textit{expression} must evaluate to a constant and can’t contain any forward-referenced symbol names. Use \texttt{ENDM} to mark the end of the repeat block. For example, this code

\begin{verbatim}
REPT 4
  SHL ax,1
ENDM
\end{verbatim}

produces the following:

\begin{verbatim}
SHL ax,1
SHL ax,1
SHL ax,1
SHL ax,1
\end{verbatim}

Another example shows how to use \texttt{REPT} in a macro to generate numbers that are the various powers of two:
count = 0
defname macro num
  Bit&num dd (1 SHL (&num))
endm
rept 32
defname %count
  count = count + 1
endm

**The WHILE directive**

You can use the **WHILE** macro directive to repeat a macro body until a certain expression evaluates to 0 (false). **WHILE** has the following syntax:

```
WHILE while_expression
  macro_body
ENDM
```

Turbo Assembler evaluates `while_expression` before each iteration of the macro body. Be careful to avoid infinite loops, which can cause Turbo Assembler to run out of memory or appear to stop functioning. Here's an example using **WHILE**:

```
WHILE 1
  IF some_condition
    EXITM
  ENDIF
  ;; Do nothing
ENDM
;; We never make it this far unless some_condition is true
```

The **EXITM** directive can be used to break out of a **WHILE** loop.

**String repeat macros**

You can use the **IRP** and **IRPC** string repeat macro directives to repeat a macro body once for each element in a list or each character in a string. Each of these directives requires you to specify a single dummy argument. Here's the **IRP** syntax:

```
IRP dummy_argument, argument_list
  macro_body
ENDM
```

**IRPC** has the following syntax:

```
IRPC dummy_argument, string
  macro_body
ENDM
```

In both cases, `dummy_argument` is the dummy argument used in the macro body. **ENDM** marks the end of the macro body.

For **IRP**, `argument_list` consists of a list of arguments separated by commas. The arguments can be any text, such as symbols, strings, numbers, and so on. The form of
each argument in the list is similar to that described for general multiline macro invocations, described earlier in this chapter. You must always surround the argument list with angle brackets (« »).

For **IRPC**, the argument consists of a single *string*. The string can contain as many characters as you want.

For each argument or character in a string, Turbo Assembler will include the macro body in the module, substituting the argument or character for the dummy argument wherever it finds it. For example,

```
IRP reg,<ax,bx,cx,dx>
PUSH reg
ENDM
```

produces the following:

```
PUSH ax
PUSH bx
PUSH cx
PUSH dx
```

and the directive **IRPC**

```
IRPC LUCKY,1379
DB LUCKY
ENDM
```

produces this:

```
DB 1
DB 3
DB 7
DB 9
```

**Note** Be careful when using **IRPC** because Turbo Assembler places each character in the string "as is" in the expanded macro, so that a string repeat macro such as

```
IRPC CHAR,HELLO
DB CHAR
ENDM
```

might not produce DB 'H', 'E', 'L', 'L', 'O', but instead would produce DB H, E, L, L, O (where each letter is treated as a symbol name).

**The % immediate macro directive**

The % immediate macro directive treats a line of text as if it's a macro body. The dummy argument names used for the macro body include all of the text macros defined at that time. Here's its syntax:

```
% macro_body_line
```

*macro_body_line* represents the macro body to use for the immediate macro expansion; for example:

```
Including multiline macro expansions in the list file

Multiline macro expansions are not normally included in the listing file. However, Turbo Assembler provides the following directives that let you list macro expansions:

- `.LALL`
- `.SALL`
- `.XALL`
- `%MACS`
- `%NOMACS`

Refer to Chapter 17 for more details on these directives.

Saving the current operating state

The `PUSHSTATE` directive saves the current operating state on an internal stack that is 16 levels deep. `PUSHSTATE` is particularly useful if you have code inside a macro that functions independently of the current operating state, but does not affect the current operating mode.

Note that you can use `PUSHSTATE` outside of macros. This can be useful for include files.

The state information that Turbo Assembler saves consists of:

- current emulation version (for example, T310)
- mode selection (for example, IDEAL, MASM, QUIRKS, MASM51)
- EMUL or NOEMUL switches
- current processor or coprocessor selection
- MULTERRS or NOMULTERRS switches
- SMART or NOSMART switches
- the current radix
- JUMPS or NOJUMPS switches
- LOCALS or NOLOCALS switches
- the current local symbol prefix

Use the `POPSTATE` directive to return to the last saved state from the stack.

Here's an example of how to use `PUSHSTATE` and `POPSTATE`.

```assembly

There are two classes of conditional directives: conditional assembly directives and conditional error-generation directives. With conditional assembly directives, you can control which code gets assembled in your program under certain conditions.

Conditional error-generation directives let you generate an assembly-time error message if certain conditions occur. Turbo Assembler displays the error message on the screen and in the listing file, and it acts like any other error message in that it prevents the emission of an object file. This chapter describes how you can use the available conditional directives.

**General conditional directives syntax**

The three types of conditional assembly directives are `IFxxx` directives, `ELSEIFxxx` directives, and `ERRxxx` directives. Use these directives as you would conditional statements in high-level languages.

**IFxxx conditional assembly directives**

You can use `IFxxx` conditional assembly directives to define blocks of code that are included in the object file if certain conditions are met (such as whether a symbol is defined or set to a particular value). Here's the syntax of a conditional assembly statement:

```assembly
IFxxx
true_conditional_body
ENDIF
```

or

```assembly
IFxxx
true_conditional_body
ELSE
```
false_conditional_body
ENDIF

Here, IFxxx represents any of the following conditional assembly directives:

- IF
- IF1
- IF2
- IFDEF
- IFNDEF
- IFB
- IFNB
- IFIDN
- IFIDNI
- IF2
- IFIDFI

Each IFxxx conditional assembly directive specifies a specific condition that evaluates to either true or false. If the condition is true, the block of assembly code in true_conditional_body is assembled into the output object file. If the condition evaluates to false, Turbo Assembler skips over true_conditional_body and does not include it in the object file. If there is an ELSE directive, the false_conditional_body is assembled into the object file if the condition is false; it's ignored if the condition is true. All conditionals are terminated with an ENDIF directive.

Note

Except for the special cases of IF1 and IF2 (which are discussed later), the two bodies of code are mutually exclusive: Either true_conditional_body will be included in the object file or false_conditional_body, but never both. Also, if you use the IFxxx...ELSE...ENDIF form, one of the two bodies will be included in the generated object file. If only the IFxxx...ENDIF form is used, true_conditional_body may or may not be included, depending on the condition.

When you nest IFs and ELSEs, ELSE always pairs with the nearest preceding IF directive.

In this example, test is a symbol that flags the inclusion of test code (if the symbol is defined, then test code is generated). color is a symbol set to nonzero if the display is color, or 0 for a monochrome display.

The actual code generated depends on these values:

:  
IFDEF test ; if test defined
  ;test code 1 ; if test defined
IFDEF color ; if color <> 0
  ;color code ; if color <> 0
ELSE ;
  ;mono code ; if color = 0
ENDIF ;
  ;test code 2 ; if test defined
ELSE ;
  ;non-test code ; if test not defined
ENDIF
Note If `test` is undefined, neither the color nor monochrome debug code based on the value of color is assembled, as this lies entirely within the conditional assembly for a defined test.

**ELSEIFxxx conditional assembly directives**

You can use the `ELSEIFxxx` as a shortcut where multiple `IF` statements are required. `ELSEIFxxx` is equivalent to an `ELSE` followed by a nested `IF`, but provides more compact code. For example,

```plaintext
IF mode EQ 0
  ;mode 0 code
ELSEIF mode LT 5
  ;mode 1-4 code
ELSE
  ;mode 5+ code
ENDIF
```

compares to

```plaintext
IF mode EQ 0
  ;mode 0 code
ELSE
  IF mode LT 5
    ;mode 1-4 code
  ELSE
    ;mode 5+ code
  ENDIF
ENDIF
```

You can't use the `ELSEIFxxx` directives outside of an `IFxxx` statement.

**ERRxxx error-generation directives**

`ERRxxx` directives generate user errors when certain conditions are met. These conditions are the same as for the `IFxxx` conditional assembly directives.

Here's the general syntax:

```
ERRxxx [arguments] [message]
```
In this case, **ERRxx** represents any of the conditional error-generating directives (such as **ERRIFB, .ERRB**, and so on).

*arguments* represents arguments that the directive might require to evaluate its condition. Some directives require an expression, some require a symbol expression, and some require one or two text expressions. Other directives require no arguments at all.

If *message* is included, it represents an optional message that’s displayed along with the error. The message must be enclosed in single (') or double (") quotation marks.

The error-generating directives generate a *user error* that is displayed onscreen and included in the listing file (if there is one) at the location of the directive in your code. If the directive specifies a message, it displays on the same line immediately following the error. For example, the directive

```
ERRIFNDEF foo "foo not defined!"
```

generates the error

```
User error: "foo not defined!"
```

if the symbol *foo* is not defined when the directive is encountered. No error would be generated in this case if *foo* were already defined.

### Specific directive descriptions

#### Unconditional error-generation directives

The unconditional error-generation directives are **ERR** and **.ERR**. These directives always generate an error and require no arguments, although they can have an optional message. You can only use **.ERR** in MASM mode.

#### Expression-conditional directives

These directives provide conditional assembly or error generation based on the results of evaluating a Turbo Assembler expression. For all of these directives, the expression must evaluate to a constant and can’t contain any forward references. If it evaluates to 0, Turbo Assembler considers the expression to be false; otherwise, it considers the expression to be true.

The following table shows conditional assembly directives that use expressions.

<table>
<thead>
<tr>
<th><strong>IFxxx directive</strong></th>
<th><strong>Assembles true conditional body if</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IF</strong> expression</td>
<td>Expression evaluates to true.</td>
</tr>
<tr>
<td><strong>IFE</strong> expression</td>
<td>Expression evaluates to false.</td>
</tr>
<tr>
<td><strong>ELSEIF</strong> expression</td>
<td>Expression evaluates to true.</td>
</tr>
<tr>
<td><strong>ELSEIFE</strong> expression</td>
<td>Expression evaluates to false.</td>
</tr>
</tbody>
</table>
The following table shows the error-generation directives that use expressions.

**Table 15.2** Error-generation directives using expressions

<table>
<thead>
<tr>
<th>Directive</th>
<th>Generates user error if</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRIF expression</td>
<td>Expression evaluates to true.</td>
</tr>
<tr>
<td>.ERRNZ expression</td>
<td>Expression evaluates to true (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFE expression</td>
<td>Expression evaluates to false.</td>
</tr>
<tr>
<td>.ERRE expression</td>
<td>Expression evaluates to false (MASM mode only).</td>
</tr>
</tbody>
</table>

**Symbol-definition conditional directives**

These directives provide conditional assembly or error generation based on whether one or more symbols are defined. These symbols are organized into a symbol expression.

A symbol expression is an expression made up of symbol names, the Boolean operators AND, OR, and NOT, and parentheses. In a symbol expression, each symbol name is treated as a Boolean value that evaluates to true if the symbol currently exists, or false if the symbol does not exist (even if it’s defined later in the module). Turbo Assembler combines these values using the Boolean operators to produce a final true or false result. In its simplest form, a symbol expression consists of a single symbol name and evaluates to true if the symbol is defined. The parsing and syntax rules for symbol_expression are similar to those for other Turbo Assembler expressions.

For example, if the symbol *foo* is defined but the symbol *bar* is not, the following symbol-expression evaluations are returned:

**Table 15.3** Evaluation of defined and undefined symbol

<table>
<thead>
<tr>
<th>Symbol expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>True</td>
</tr>
<tr>
<td>bar</td>
<td>False</td>
</tr>
<tr>
<td>not foo</td>
<td>False</td>
</tr>
<tr>
<td>not bar</td>
<td>True</td>
</tr>
<tr>
<td>foo OR bar</td>
<td>True</td>
</tr>
<tr>
<td>foo AND bar</td>
<td>False</td>
</tr>
<tr>
<td>NOT (foo AND bar)</td>
<td>True</td>
</tr>
<tr>
<td>NOT foo OR NOT bar</td>
<td>True (same as “(NOT foo) OR (NOT bar)”</td>
</tr>
</tbody>
</table>

The directives that control assembly and use symbol expressions are shown in the following table.

**Table 15.4** Symbol-expression directives using symbol_expr

<table>
<thead>
<tr>
<th>Directive</th>
<th>Assembles true conditional body</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFDEF symbol_expr</td>
<td>symbol_expr evaluates to true.</td>
</tr>
<tr>
<td>IFNDEF symbol_expr</td>
<td>symbol_expr evaluates to false.</td>
</tr>
<tr>
<td>ELSEIFDEF symbol_expr</td>
<td>symbol_expr evaluates to true.</td>
</tr>
<tr>
<td>ELSEIFNDEF symbol_expr</td>
<td>symbol_expr evaluates to false.</td>
</tr>
</tbody>
</table>
The error-generation directives that use *symbol_expressions* are shown in the following table.

**Table 15.5  Error-generation directives**

<table>
<thead>
<tr>
<th><strong>ERRxxx directive</strong></th>
<th><strong>Generates user error if</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRIFDEF <code>symbol_expr</code></td>
<td><code>symbol_expr</code> evaluates to true.</td>
</tr>
<tr>
<td>.ERRDEF <code>symbol_expr</code></td>
<td><code>symbol_expr</code> evaluates to true (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFNDEF <code>symbol_expr</code></td>
<td><code>symbol_expr</code> evaluates to false.</td>
</tr>
<tr>
<td>.ERRNDEF <code>symbol_expr</code></td>
<td><code>symbol_expr</code> evaluates to false (MASM mode only).</td>
</tr>
</tbody>
</table>

For example, the following error-generating conditionals are equivalent, and would generate an error only if both *foo* and *bar* are currently defined:

```
ERRIFDEF foo AND bar
ERRIFNDEF NOT ( foo AND bar )
ERRIFNDEF NOT foo OR NOT bar
```

**Text-string conditional directives**

These directives provide conditional assembly or error generation based on the contents of *text_string*. A *text_string* can be either a string constant delineated by brackets (<>) or a text macro name preceded by a percent sign (%). For example,

```
<ABC> ; text string ABC
%foo ; the contents of text macro foo
```

**Note**  See Chapter 14 for information about how to define and manipulate text macros.

The conditional assembly directives that use *text_string* are shown in the following table:

**Table 15.6  Conditional assembly directives using *text_string***

<table>
<thead>
<tr>
<th><strong>IFxxx directive</strong></th>
<th><strong>Assembles true_conditional_body if</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>IFNB <code>txt_str</code></td>
<td><code>txt_str</code> is not blank.</td>
</tr>
<tr>
<td>IFB <code>txt_str</code></td>
<td><code>txt_str</code> is blank (empty).</td>
</tr>
<tr>
<td>IFIDN <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are identical text strings.</td>
</tr>
<tr>
<td>IFINDI <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are identical text strings, ignoring case distinctions.</td>
</tr>
<tr>
<td>IFDIF <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are different text strings.</td>
</tr>
<tr>
<td>IFDIFI <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are different text strings, ignoring case distinctions.</td>
</tr>
<tr>
<td>ELSEIFNB <code>txt_str</code></td>
<td><code>txt_str</code> is not blank.</td>
</tr>
<tr>
<td>ELSEIFB <code>txt_str</code></td>
<td><code>txt_str</code> is blank (empty).</td>
</tr>
<tr>
<td>ELSEIFIDN <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are identical text strings.</td>
</tr>
<tr>
<td>ELSEIFIDNI <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are identical text strings, ignoring case distinctions.</td>
</tr>
<tr>
<td>ELSEIFDIF <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are different text strings.</td>
</tr>
<tr>
<td>ELSEIFDIFI <code>txt_str1, txt_str2</code></td>
<td><code>txt_str1</code> and <code>txt_str2</code> are different text strings, ignoring case distinctions.</td>
</tr>
</tbody>
</table>
The error-generation directives that use text_string are shown in Table 15.7:

<table>
<thead>
<tr>
<th>Table 15.7</th>
<th>Error-generation directives using text_strings</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRxx directive</td>
<td>Generates user error if</td>
</tr>
<tr>
<td>ERRIFNB txt_str</td>
<td>txt_str is not blank.</td>
</tr>
<tr>
<td>ERRNB txt_str</td>
<td>txt_str is not blank (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFB txt_str</td>
<td>txt_str is blank (null).</td>
</tr>
<tr>
<td>ERRB txt_str</td>
<td>txt_str is blank (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFIDN txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are identical text strings.</td>
</tr>
<tr>
<td>ERRIDN txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are identical text strings (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFIDNI txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are identical text strings, ignoring case distinctions.</td>
</tr>
<tr>
<td>ERRIDNI txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are identical text strings, ignoring case distinctions (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFDIF txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are different text strings.</td>
</tr>
<tr>
<td>ERRDIF txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are different text strings (MASM mode only).</td>
</tr>
<tr>
<td>ERRIFDIFI txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are different text strings, ignoring case distinctions.</td>
</tr>
<tr>
<td>ERRDIFI txt_str1, txt_str2</td>
<td>txt_str1 and txt_str2 are different text strings, ignoring case distinctions (MASM mode only).</td>
</tr>
</tbody>
</table>

Use these directives to check the arguments passed to macros. (Note that they are not restricted to use within macros.)

When used within a macro definition, IFB and IFNB can determine whether you’ve supplied the proper number of arguments to the macro. When invoking a macro, Turbo Assembler does not generate an error message if you’ve supplied too few arguments; instead, the unspecified arguments are blank. In this way, you can define a macro that may take arguments. For example,

```plaintext
:...
load MACRO addr,reg
  IFNB <reg>
    MOV reg,addr
  ELSE
    MOV ax,addr
  ENDIF
ENDM
:...
```

You could invoke this example with `load test,cx`, which would generate a `mov cx,test` instruction (or invoke simply `load test`, which will generate a `mov ax,test` instruction because the second parameter is blank). Alternately, you could use ERRIFB to generate an error for a macro invocation with a missing critical argument. Thus,

```plaintext
:...
load MACRO addr
  ERRIFB <addr>
    MOV ax,addr
ENDM
:...
```
generates an error when invoked with `load`, but would not when invoked with `load test`.

### Assembler-pass conditionals

These directives provide conditional assembly or error generation based on the current assembly pass:

<table>
<thead>
<tr>
<th>IFxxx directive</th>
<th>Assembles true conditional body if</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF1</td>
<td>Assembler pass 1</td>
</tr>
<tr>
<td>IF2</td>
<td>Assembler pass 2</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ERRxxx directive</th>
<th>Generates user error if</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERRIF1</td>
<td>Assembling pass 1</td>
</tr>
<tr>
<td>.ERR1</td>
<td>Assembling pass 1 (MASM mode only)</td>
</tr>
<tr>
<td>ERRIF2</td>
<td>Assembling pass 2</td>
</tr>
<tr>
<td>.ERR2</td>
<td>Assembling pass 2 (MASM mode only)</td>
</tr>
</tbody>
</table>

Normally, Turbo Assembler acts as a single-pass assembler. If you use Turbo Assembler’s multi-pass capability (invoked with the `/m` command-line switch), multiple passes are used if necessary.

Since there is always at least one pass through the assembler, the `IF1` conditional assembly directive will always assemble the code in its conditional block, and the `.ERR1` and `ERRIF1` directives will always generate an error (but only during the first assembly pass).

If you use any of these directives and have not enabled multiple passes, Turbo Assembler will generate Pass dependent construction warnings for all of these directives to alert you to a potentially hazardous code omission. If you enable multiple passes, Turbo Assembler will perform exactly two passes, and will generate the warning `Maximum compatibility pass was done`.

### Including conditionals in the list file

Normally, false conditional assembly code is not included in a listing file. You can override this through the use of assembler directives and command-line switches.

*Note* See Chapter 2 and Chapter 17 for further information on this subject.
Interfacing with the linker

Modular programs are typically constructed from several independent sections of code, called modules. The compiler processes each of these modules independently, and the linker (TLINK) puts the resulting pieces together to create an executable file. The README file explains where you can find information about how to use TLINK, but it's also important to know how to define and include all the files and libraries you might want prior to linking. This chapter describes how to do these things.

Publishing symbols externally

You may find that you'll need to use some variables and procedures in all of your program modules. Turbo Assembler provides several directives that let you define symbols and libraries so that you can use them globally, as well as use communal variables (which the linker allocates space for). You'll also have to be careful about how you name your symbols, since different languages have particular requirements. The next few sections discuss these directives and naming requirements.

Conventions for a particular language

When you name symbols that you plan to use externally, remember to use the language specifier for your particular language. These requirements for variable names are:

- Pascal: uppercase characters
- C/C++: name must start with _, Rest of name should be in lowercase characters (_name).

When you specify a language in the MODEL directive or in the PROC declaration, or declare the language in a symbol's PUBLIC declaration, Turbo Assembler will automatically use the proper naming conventions for that language, as follows:
- C, CPP, and PROLOG use the C/C++ naming conventions.
- BASIC, PASCAL, FORTRAN, and NOLANGUAGE languages use the Pascal naming conventions.
- SYSCALL specifies C calling conventions, but without prepending underscores to symbol names (like Pascal naming conventions).
- STDCALL uses C calling conventions for procedures with variable arguments, and Pascal calling conventions for procedures with fixed arguments. It always uses the C naming convention.

The /m1 switch (described in Chapter 2) tells Turbo Assembler to treat all symbol names as case sensitive. The /mx switch (also described in Chapter 2) tells the assembler to treat only external and public symbols as case sensitive, and that all other symbols within the source file are uppercase. When you use these two switches together, they have a special meaning for symbols declared as Pascal: These switches cause the symbols in question to be published as all uppercase to the linker.

### Declaring public symbols

When you declare a public symbol, you intend it to be accessible from other modules. The following types of symbols can be public:

- data variable names
- program labels
- numeric constants defined with EQU

You can use the PUBLIC directive to define public symbols. Its syntax follows:

```
PUBLIC [language] symbol [, [language] symbol] ...
```

Notice that in order to use public symbols outside the module where they’re defined, you must use the EXTRN directive.

`language` is either C, CPP, PASCAL, BASIC, FORTRAN, PROLOG, or NOLANGUAGE, and defines any language-specific conventions to be applied to the symbol name. Using a language in the PUBLIC directive temporarily overrides the current language setting (the default, NOLANGUAGE, or one that you’ve established with .MODEL).

Turbo Assembler publishes `symbol` in the object file so that other modules can access it. If you don’t make a symbol public, you can access it only from the current source file; for example:

```
PUBLIC XYPROC ; make procedure public
XYPROC PROC NEAR
```

### Declaring library symbols

You can also use symbols as dynamic link entry points for a dynamic link library. Use the PUBLICDLL directive to declare symbols to be accessible this way. Here’s its syntax:

```
PUBLICDLL [language] symbol [, [language] symbol] ...
```
Turbo Assembler publishes symbol in the object file as a dynamic link entry point (using EXPDEF and IMPDEF records) so that it can be accessed by other programs. language causes any language-specific conventions to be applied to the symbol name. Valid language specifiers are C, PASCAL, BASIC, FORTRAN, PROLOG, and NOLANGUAGE.

Here's an example of code using PUBLICDLL:

```assembly
PUBLICDLL XYPROC
XYPROC PROC NEAR
```

;make procedure XYPROC

;accessible as dynamic link entry point

---

### Defining external symbols

External symbols are symbols that are defined outside a module, that you can use within the module. These symbols must have been declared using the PUBLIC directive. EXTRN has the following syntax:

```
EXTRN definition [,definition] ...
```

definition describes a symbol and has the following format:

```
[language] name [[count1]] :complex_type [:count2]
```

### Defining global symbols

Global symbols function like public symbols, without your having to specify a PUBLIC or an EXTRN. If the variable is defined in the module, it functions like PUBLIC. If not, it functions like EXTRN. You can use the GLOBAL directive to define global symbols. GLOBAL has the same syntax as PUBLIC and EXTRN (see the previous few sections for syntax descriptions.)

GLOBAL lets you have an INCLUDE file included by all source files; the INCLUDE file contains all shared data defined as global symbols. When you reference these data items in each module, the GLOBAL definition acts as an EXTRN directive, describing how the data is defined in another module.

You must define a symbol as GLOBAL before you first use it elsewhere in your source file. Also note that each argument of GLOBAL accepts the same syntax as an argument of EXTRN.

Here's an example:

```assembly
GLOBAL X:WORD, Y:BYTE
```

X DW 0

;made public for other module

mov al, Y

;Y is defined as external

---

### Publishing a procedure prototype

If you’re using version T320 or later and you use PROCDESC to describe a procedure prototype, Turbo Assembler treats the procedure name as if it were a GLOBAL symbol. If you’ve defined the procedure within the module, it is treated as PUBLIC. Otherwise, Turbo Assembler assumes it to be EXTRN.
You can place PROCDESC directives in an include file. When you reference the procedure name in the module, PROCDESC acts as an EXTRN directive, describing how the procedure is defined in another module. If the procedure is defined in the module, PROCDESC acts as a PUBLIC directive to publish the procedure.

### Defining communal variables

Communal variables function like external variables, with a major difference: communal variables are allocated by the linker. Communal variables are actually like global variables, but you can’t assign them initial values. These uninitialized variables can be referenced from multiple modules.

One drawback to using communal variables is that there’s no guarantee they’ll appear in consecutive memory locations. If this is an issue for you, use global variables instead.

You can use the COMM directive to define a communal variable. Here’s its syntax:

```
COMM definition [,definition]...
```

Each definition describes a symbol and has the following format:

```
[distance] [language] symbolname[[count1]]:complex_type [:count2]
```

- `distance` is optional and can be either NEAR or FAR. If you don’t specify a distance, it will default to the size of the default data memory model. If you’re not using the simplified segmentation directives, the default size is NEAR. With the tiny, small, and medium models, the default size is also NEAR; all other models are FAR.
- `language` is either C, PASCAL, BASIC, FORTRAN, PROLOG, or NOLANGUAGE. Using a language in the COMM directive temporarily overrides the current language setting (default or one established with .MODEL). Note that you don’t need to have a .MODEL directive in effect to use this feature.
- `symbolname` is the symbol that is to be communal and have storage allocated at link time. `symbolname` can also specify an array element size multiplier `count1` to be included in the total space computation. If distance is NEAR, the linker uses `count1` to calculate the total size of the array. If distance is FAR, the linker uses `count2` to indicate how many elements there are of size `count1` times the basic element size (determined by type). `count1` defaults to a value of 1.
- `complex_type` is the data type of the argument. It can be either a simple type, or a complex pointer expression. See Chapter 5 for more information about the syntax of complex types.

The optional `count2` specifies how many items this communal symbol defines. If you do not specify a `count2`, a value of 1 is assumed. The total space allocated for the communal variable is `count2` times the length specified by the `type` field times `count1`.

In MASM mode, communal symbols declared outside of any segment are presumed to be reachable using the DS register, which may not always be a valid assumption. Make sure that you either place the correct segment value in DS or use an explicit segment override when referring to these variables. In Ideal mode, Turbo Assembler correctly checks for whether the communal variable is addressable, using any of the current segment registers as described with the ASSUME directive.
Here's an example using the COMM directive.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMM buffer:BYTE:512</td>
<td>512 bytes allocated at link time</td>
</tr>
<tr>
<td>COMM abc[41]:WORD:10</td>
<td>820 bytes (10 items of 41 words; each) allocated at link time</td>
</tr>
<tr>
<td>COMM FAR abc[41]:WORD:10</td>
<td>10 elements of 82 bytes (2 bytes; times 41 elements) allocated at link time</td>
</tr>
</tbody>
</table>

**Including a library**

For the times when you know that your source file will always need to use routines in a specified library, you can use the INCLUDELIB directive. Using INCLUDELIB also prevents you from having to remember to specify the library name in the linker commands; INCLUDELIB tells the linker to include a particular library. The appropriate syntaxes for this directive are:

**Ideal mode:**

```
INCLUDELIB "filename" ;note the quotes!
```

**MASM mode:**

```
INCLUDELIB filename
```

*filename* is the name of the library you want the linker to include at link time. If you don’t supply an extension with *filename*, the linker assumes .LIB.

Here’s an example:

```
INCLUDELIB "diskio" ;includes DISKIO.LIB
```

**The ALIAS directive**

Turbo Assembler supports ALIAS to allow the association of an alias name with a substitute name. When the linker encounters an alias name, it resolves the alias by referring to the substitute name.
Generating a listing

A listing file is useful if you want to see exactly what Turbo Assembler generates when each instruction or directive is assembled. The file is basically the source file annotated with a variety of information about the results of the assembly. Turbo Assembler lists the actual machine code for each instruction, along with the offset in the current segment of the machine code for each line. What's more, Turbo Assembler provides tables of information about the labels and segments used in the program, including the value and type of each label, and the attributes of each segment. For additional information on creating listings, refer to the /I and /la command-line switches documented in Chapter 2.

Turbo Assembler can also, on demand, generate a cross-reference table for all labels used in a source file, showing you where each label was defined and where it was referenced. See the /c command-line option in Chapter 2 for more information on generating cross-reference tables.

Listing format

The top of each page of the listing file displays a header consisting of the version of Turbo Assembler that assembled the file, the date and time of assembly, and the page number within the listing.

There are two parts to the listing file: the annotated source code listing and the symbol tables. The original assembly code is displayed first, with a header containing the name of the file where the source code resides. The assembler source code is annotated with information about the machine code Turbo Assembler assembled from it. Any errors or warnings encountered during assembly are inserted immediately following the line they occurred on.

The code lines in the listing file follow this format:

<depth> <line number> <offset> <machine code> <source>

<depth> indicates the level of nesting of Include files and macros within your listing file.
<line number> is the number of the line in the listing file (not including header and title lines). Line numbers are particularly useful when the cross-reference feature of Turbo Assembler, which refers to lines by line number, is used. Be aware that the line numbers in <line number> are not the source module line numbers. For example, if a macro is expanded or a file is included, the line-number field will continue to advance, even though the current line in the source module stays the same. To translate a line number (for example, one that the cross-referencer produced) back to the source file, you must look up the line number in the listing file, and then find that same line (by eye, not by number) in the source file.

<offset> is the offset in the current segment of the start of the machine code generated by the associated assembler source line.

<machine code> is the actual sequence of hexadecimal byte and word values that is assembled from the associated assembler source line.

<source> is simply the original assembler line, comments and all. Some assembler lines, such as those that contain only comments, don't generate any machine code; these lines have no <offset> or <machine code> fields, but do have a line number.

**General list directives**

There are a variety of list directives that let you control what you want in your listing file. The general list directives follow:

- **.LIST** ;MASM mode only
- **.XLIST** ;MASM mode only
- **%LIST**
- **%NOLIST**
- **%CTLS**
- **%NOCTLS**
- **%SYMS**
- **%NOSYMS**

The **%LIST** directive shows all of the source lines in your listing. This is the default condition when you create a listing file. To turn off the display of all the source lines, use the **%NOLIST** directive. Here's an example:

```assembly
%NOLIST ;turn off listing
INCLUDE MORE .INC
%LIST ;turn on listing
```

The **.LIST** and **.XLIST** directives function the same way as **%LIST** and **%NOLIST**. Here's an example:

```assembly
.LIST
jmp xyz ;this line always listed
.XLIST
add dx,ByteVar ;not in listing
```

You can use the **%CTLS** and **%NOCTLS** directives to control the listing directives. **%CTLS** causes listing control directives (such as **%LIST**, **%INCL**, and so on) to be
placed in the listing file; normally, they are not listed. It takes effect on all subsequent lines, so the %CTLS directive itself will not appear in the listing file. %NOCTLS reverses the effect of a previous %CTLS directive. After issuing %NOCTLS, all subsequent listing-control directives will not appear in the listing file. (%NOCTLS is the default listing-control mode that Turbo Assembler uses when it starts assembling a source file.); for example,

\[
\begin{align*}
&\text{%CTLS} \\
&\text{%NOLIST} \quad ; \text{this will be in listing file} \\
&\text{%NOCTLS} \\
&\text{%LIST} \quad ; \text{this will not appear in listing}
\end{align*}
\]

You can use the %SYMS and %NOSYMS directives to cause the symbol table to either appear or not to appear in your listing file (the default is for it to appear). The symbol table will appear at the end of the listing file.

Here’s the syntax for %SYMS:

\[
\text{%SYMS}
\]

Here’s the syntax for %NOSYMS:

\[
\text{%NOSYMS}
\]

Include file list directives

In the event that you might want to list the include files in your listing file, you can turn this capability on and off using the %INCL and %NOINCL directives. By default, INCLUDE files are normally contained in the listing file. %NOINCL stops all subsequent INCLUDE files source lines from appearing in the listing until a %INCL is enabled. This is useful if you have a large INCLUDE file that contains things such as a lot of EQU definitions that never change.

Here’s an example:

\[
\begin{align*}
&\text{%INCL} \\
&\text{INCLUDE DEFS.INC} \quad ; \text{contents appear in listing} \\
&\text{%NOINCL} \\
&\text{INCLUDE DEF1.INC} \quad ; \text{contents don't appear}
\end{align*}
\]

Conditional list directives

When you have conditional blocks of code in your source files, you might not want all of that information to appear in the listing file. Showing conditional blocks can be very helpful in some instances when you want to see exactly how your code is behaving. Turbo Assembler provides the following conditional list directives:

- %LFCOND ; MASM mode only
- %SFCOND ; MASM mode only
- %TFCOND ; MASM mode only
- %CONDS
- %NOCONDS
Turbo Assembler does not usually list conditional blocks.

The %CONDS directive displays all statements in conditional blocks in the listing file. This includes the listing of false conditional blocks in assembly listings. The .LFCOND directive functions the same as %CONDS. %NOCONDS prevents statements in false conditional blocks from appearing in the listing file. The .SFCONDS directive functions exactly the same as %NOCOND. If you want to toggle conditional block-listing mode, use the .TFCOND directive.

The first .TFCOND that Turbo Assembler encounters enables a listing of conditional blocks. If you use the /X command-line option, conditional blocks start off being listed, and the first .TFCOND encountered disables listing them. Each time .TFCOND appears in the source file, the state of false conditional listings is reversed.

To invoke any of these directives, place it by itself on a line in your code. They will affect the conditional blocks that immediately follow them.

**Macro list directives**

Macro expansions are not normally included in listing files. Having this information in listing files can be very helpful when you want to see what your code is doing. Turbo Assembler provides several directives that let turn this feature on and off. They are:

- .LALL ;MASM mode only
- .SALL ;MASM mode only
- .XALL ;MASM mode only
- %MACS
- %NOMACS

The %MACS directive enables the listing of macro expansions. The .LALL directive does the same thing, but only works in MASM mode. You can use these macros to toggle macro expansion in listings on.

%MACS has the following syntax:

```
%MACHS
```

You can specify .LALL as follows:

```
.LALL
```

If you want to suppress the listing of all statements in macro expansions, use either the %NOMACS or .SALL directives. Note that you can use these directives to toggle macro expansion in listings off.

%NOMACS has the following syntax:

```
%NOMACS
```

You can specify .SALL as follows:

```
.SALL
```

The .XALL directive, which is only available in MASM mode, lets you list only the macro expansions that generate code or data. .XALL has the syntax .XALL.
Cross-reference list directives

The symbol table portion of the listing file normally tells you a great deal about labels, groups, and segments, but there are two things it doesn’t tell you: where labels, groups, and segments are defined, and where they’re used. Cross-referenced symbol information makes it easier to find labels and follow program execution when debugging a program.

There are several ways of enabling cross-referencing information in your listing file. You can use /c to produce cross-referencing information for an entire file (see Chapter 2 for details), or you can include directives in your code that let you enable and disable cross-referencing in selected portions of your listings. These directives are:

- `.CREF' ;MASM mode only
- `.XCREF' ;MASM mode only
- `%CREF
- `%NOCREF
- `%CREFALL
- `%CREFREF
- `%CREFUREF

Turbo Assembler includes cross referencing information in the listing file. In addition, you can specify a .XRF file in your Turbo Assembler command to get a separate .XRF file.

The `%CREF and .CREF directives let you accumulate cross-reference information for all symbols encountered from that point forward in the source file. %CREF and .CREF reverse the effects of any `%NOCREF or .XCREF directives, which inhibit the collection of cross-reference information.

%CREF and .CREF have the following syntaxes:

```
%CREF
```

or

```
.CREF
```

%NOCREF and .XCREF have the following syntaxes:

```
%NOCREF [symbol, ...]
```

or

```
.XCREF [symbol, ...]
```

If you use `%NOCREF or .XCREF alone without specifying any symbols, cross-referencing is disabled completely. If you supply one or more symbol names, cross-referencing is disabled only for those symbols.

The `%CREFALL directive lists all symbols in the cross reference. %CREFALL reverses the effect of any previous `%CREFREF (which disables listing of unreferenced symbols in the cross reference), or `%CREFUREF (which lists only the unreferenced symbols in the cross reference). After issuing `%CREFALL, all subsequent symbols in the source file
will appear in the cross-reference listing. This is the default mode that Turbo Assembler uses when assembling your source file.

The syntax for %CREFALL, %CREFREF, and %CREFUREF follows:

```
%CREFALL
%CREFREF
%CREFUREF
```

## Changing list format parameters

The listing format control directives alter the format of the listing file. You can use these directives to tailor the appearance of the listing file to your tastes and needs.

The **PAGE** directive sets the listing page height and width, and starts new pages. **PAGE** only works in MASM mode. **PAGE** has the following syntax:

```
PAGE [rows] [,cols]
PAGE +
```

*rows* specifies the number of lines that will appear on each listing page. The minimum is 10 and the maximum is 255. *cols* specifies the number of columns wide the page will be. The minimum width is 59; the maximum is 255. If you omit either *rows* or *cols*, the current setting for that parameter will remain unchanged. To change only the number of columns, precede the column width with a comma; otherwise, you'll end up changing the number of rows instead.

If you follow the **PAGE** directive with a plus sign (+), a new page starts, the section number is incremented, and the page number restarts at 1. If you use **PAGE** with no arguments, the listing resumes on a new page, with no change in section number.

The **%PAGESIZE** directive functions exactly like the **PAGE** directive, except that it doesn't start a new page and that it works in both MASM and Ideal modes. **%PAGESIZE** has the following syntax:

```
%PAGESIZE [rows] [,cols]
```

**%NEWPAGE** functions like **PAGE**, with no arguments. Source lines appearing after **%NEWPAGE** will begin at the start of a new page in the listing file. **%NEWPAGE** has the following syntax:

```
%NEWPAGE
```

The **%BIN** directive sets the width of the object code field in the listing file. **%BIN** has the following syntax:

```
%BIN size
```

*size* is a constant. If you don’t use this directive, the instruction opcode field takes up 20 columns in the listing file. For example,

```
%BIN 12 ;set listing width to 12 columns
```
%DEPTH sets the size of the depth field in the listing file. %DEPTH has the following syntax:

%DEPTH width

*width* specifies how many columns to reserve for the nesting depth field in the listing file. The depth field indicates the nesting level for INCLUDE files and macro expansions. If you specify a width of 0, this field does not appear in the listing file. Usually, you won't need to specify a width of more than 2, since that would display a depth of up to 99 without truncation. The default width for this field is 1 column.

%LINUM sets the width of the line-number field in the listing file. %LINUM has the following syntax:

%LINUM size

%LINUM lets you set how many columns the line numbers take up in the listing file. *size* must be a constant. If you want to make your listing as narrow as possible, you can reduce the width of this field. Also, if your source file contains more than 9,999 lines, you can increase the width of this field so that the line numbers are not truncated. The default width for this field is 4 columns.

%TRUNC truncates listing fields that are too long. %TRUNC has the following syntax:

%TRUNC

The object code field of the listing file has enough room to show the code emitted for most instructions and data allocations. You can adjust the width of this field with %BIN. If a single source line emits more code than can be displayed on a single line, the rest is normally truncated and therefore not visible. When you want to see all the code generated, use %NOTRUNC (which word-wraps too-long fields in the listing file). Otherwise, use %TRUNC. You can use these directives to toggle truncation on and off.

%NOTRUNC has the following syntax:

%NOTRUNC

%PCNT sets the segment:offset field width in the listing file. %PCNT has the following syntax:

%PCNT width

where *width* is the number of columns you want to reserve for the offset within the current segment being assembled. Turbo Assembler sets the width to 4 for ordinary 16-bit segments and sets it to 8 for 32-bit segments used by the 386 processor. %PCNT overrides these defaults.

The TITLE directive, which you can use only in MASM mode, sets the title in the listing file. TITLE has the following syntax:

TITLE text

The title *text* appears at the top of each page, after the name of the source file and before any subtitle set with the SUBTTL directive. You can use TITLE as many times as you want.
%TITLE functions like TITLE, but you can use it for either MASM or Ideal mode. %TITLE has the following syntax:

\$TITLE "text"

SUBTTL, which only works in MASM mode, sets the subtitle in the listing file. SUBTTL has the following syntax:

\$SUBTTL text

The subtitle appears at the top of each page, after the name of the source file, and after any title set with TITLE.

You can place as many SUBTTL directives in your program as you wish. Each directive changes the subtitle that will appear at the top of the next listing page.

%SUBTTL functions like SUBTTL, but it works in both MASM and Ideal modes. %SUBTTL has the following syntax:

\$SUBTTL "text"

%TABSIZE sets the tab column width in the listing file. %TABSIZE has the following syntax:

\$TABSIZE width

width is the number of columns between tabs in the listing file. The default tab column width is 8 columns.

You can use the %TEXT directive to set the width of the source field in the listing file. It has the following syntax:

\$TEXT width

width is the number of columns to use for source lines in the listing file. If the source line is longer than this field, it will either be truncated or wrapped to the following line, depending on whether you’ve used %TRUNC or %NOTRUNC.

You can use the %PUSHLCTL directive to save the listing controls on a 16-level stack. It only saves the listing controls that can be enabled or disabled (%INCL, %NOINCL, and so on). The listing field widths are not saved. This directive is particularly useful in macros, where you can invoke special listing modes that disappear once the macro expansion terminates.

%PUSHLCTL has the following syntax:

\$PUSHLCTL

Conversely, the %POPLCTL directive recalls listing controls from the stack. Here’s its syntax:

\$POPLCTL

%POPLCTL resets the listing controls to the way they were when the last %PUSHLCTL directive was issued. None of the listing controls that set field width are restored (such as %DEPTH, %PCNT).
While many programmers can—and do—develop entire programs in assembly language, many others prefer to do the bulk of their programming in a high-level language, dipping into assembly language only when low-level control or very high-performance code is required. Still others prefer to program primarily in assembler, taking occasional advantage of high-level language libraries and constructs.

Borland C++ lends itself particularly well to supporting mixed C++ and assembler code on an as-needed basis, providing not one but three mechanisms for integrating assembler and C++ code. The inline assembly feature of Borland C++ provides a quick and simple way to put assembler code directly into a C++ function. You can assemble the inline code with Turbo Assembler or use Borland C++'s built-in assembler. For further information about using in-line assembly in Borland C++ or the built-in assembler, see the Borland C++ Programmer’s Guide. For those who prefer to do their assembler programming in separate modules written entirely in assembly language, Turbo Assembler modules can be assembled separately and linked to Borland C++ code.

First, we’ll discuss the details of linking separately assembled Turbo Assembler modules to Borland C++, and explore the process of calling Turbo Assembler functions from Borland C++ code. Then, we’ll cover calling Borland C++ functions from Turbo Assembler code.

**Calling Turbo Assembler functions from Borland C++**

C++ and assembler have traditionally been mixed by writing separate modules entirely in C++ or assembler, compiling the C++ modules and assembling the assembler modules, and then linking the separately compiled modules together. Borland C++ modules can readily be linked with Turbo Assembler modules in this fashion.
The executable file is produced from mixed C++ and assembler source files. You start this cycle with

```
bcc filenaml.cpp filenam2.asm
```

This instructs Borland C++ to first compile FILENAM1.CPP to FILENAM1.OBJ, then invoke Turbo Assembler to assemble FILENAM2.ASM to FILENAM2.OBJ, and finally invoke TLINK to link FILENAM1.OBJ and FILENAM2.OBJ into FILENAM1.EXE.

Separate compilation is very useful for programs that have sizable amounts of assembler code, since it makes the full power of Turbo Assembler available and allows you to do your assembly language programming in a pure assembler environment, without the `asm` keywords, extra compilation time, and C++-related overhead of inline assembly.

There is a price to be paid for separate compilation: The assembler programmer must attend to all the details of interfacing C++ and assembler code. Where Borland C++ handles segment specification, parameter-passing, reference to C++ variables, register variable preservation, and the like for inline assembly, separately compiled assembler functions must explicitly do all that and more.

There are two major aspects to interfacing Borland C++ and Turbo Assembler. First, the various parts of the C++ and assembler code must be linked together properly, and functions and variables in each part of the code must be made available to the rest of the code as needed. Second, the assembler code must properly handle C-style function calls. This includes accessing passed parameters, returning values, and following the register preservation rules required of C++ functions.

Let’s start by examining the rules for linking together Borland C++ and Turbo Assembler code.

### The framework

In order to link Borland C++ and Turbo Assembler modules together, three things must happen:

- The Turbo Assembler modules must use a Borland C++-compatible segment-naming scheme.
- The Borland C++ and Turbo Assembler modules must share appropriate function and variable names in a form acceptable to Borland C++.
- TLINK must be used to combine the modules into an executable program.

This says nothing about what the Turbo Assembler modules actually do; at this point, we’re only concerned with creating a framework within which C++-compatible Turbo Assembler functions can be written.

### Linking assembly language modules with C++

Type-safe linkage is an important concept in C++. The compiler and linker must work together to ensure function calls between modules use the correct argument types. A process called `name-mangling` provides the necessary argument type information.
Name-mangling modifies the name of the function to indicate what arguments the function takes.

When you build a program entirely in C++, name-mangling occurs automatically and transparently. However, when you write a module in assembly language to be linked into a C++ program, you must be sure the assembler module contains mangled names. You can do this easily by writing a dummy function in C++ and compiling it to assembler. The .ASM file that Borland C++ generates will have the proper mangled names. You use these names when you write the real assembler module.

For example, the following code fragment defines four different versions of the function named test:

```c
void test ()
{
}

void test( int )
{
}

void test( int, int )
{
}

void test( float, double )
{
}
```

If the code is compiled using the -S option, the compiler produces an assembly language output file (.ASM). This is how the output looks (edited to remove extraneous details):

```asm
; void test()
@test$qv proc near
    push bp
    mov bp, sp
    pop bp
    ret
@test$qv endp

; void test( int )
@test$qi proc near
    push bp
    mov bp, sp
    pop bp
    ret
@test$qi endp

; void test( int, int )
@test$qii proc near
    push bp
    mov bp,sp
    pop bp
    ret
@test$qii endp

; void test( float, double )
```

Chapter 18, Interfacing Turbo Assembler with Borland C++ 199
Using Extern "C" to simplify linkage

If you prefer, you can use unmangled names for your assembler functions, instead of trying to figure out what the mangled names would be. Using unmangled names will protect your assembler functions from possible future changes in the name-mangling algorithm. Borland C++ allows you to define standard C function names in your C++ programs.

Look at this example:

```c
extern "C" {
    int add(int *a, int b);
}
```

Any functions declared within the braces will be given C style names. Here is the matching assembler procedure definition.

```assembly
public _add
_add proc
```

Declaring an assembler function with an extern "C" block can save you the trouble of determining what the mangled names will be. Your code will be more readable, also.

Memory models and segments

For a given assembler function to be callable from C++, that function must use the same memory model as the C++ program and must use a C++-compatible code segment. Likewise, in order for data defined in an assembler module to be accessed by C++ code (or for C++ data to be accessed by assembler code), the assembler code must follow C++ data segment-naming conventions.

Memory models and segment handling can be quite complex to implement in assembler. Fortunately, Turbo Assembler does virtually all the work of implementing Borland C++-compatible memory models and segments for you in the form of the simplified segment directives.

Simplified segment directives and Borland C++

The .MODEL directive tells Turbo Assembler that segments created with the simplified segment directives should be compatible with the selected memory model (tiny, small, compact, medium, large, huge, or tchuge), and controls the default type (near or far) of procedures created with the PROC directive. Memory models defined with the .MODEL directive are compatible with the equivalently named Borland C++ models except that you should use Turbo Assembler's tchuge memory model when you want to support Borland C++'s huge memory model. (The huge memory model is more appropriate for compatibility with other C compilers.) You should use the FARSTACK modifier with the .MODEL directive for large model, so the stack does not become a part of DGROUP.
Finally, the .CODE, .DATA, .DATA?, .FARDATA, and .FARDATA? simplified segment directives generate Borland C++-compatible segments. (Don't use .DATA? or FARDATA? in huge model as they do not exist in Borland C++)

For example, consider the following Turbo Assembler module, named DOTOTAL.ASM:

```assembly
; select Intel-convention segment ordering
.MODEL small ; select small model (near code and data)
.DATA ; TC-compatible initialized data segment
EXTRN _Repetitions:WORD ; externally defined
PUBLIC _StartingValue ; available to other modules
_StartingValue DW 0
.DATA? ; TC-compatible uninitialized data segment
RunningTotal DW ?
.CODE ; TC-compatible code segment
PUBLIC _DoTotal
_DoTotal PROC ; function (near-callable in small model)
mov cx,[_Repetitions] ; # of counts to do
mov ax,[_StartingValue]
mov [RunningTotal],ax ; set initial value
TotalLoop:
inc [RunningTotal] ; RunningTotal++
loop TotalLoop
mov ax, [RunningTotal] ; return final total
ret
_DoTotal ENDP
END
```

The assembler procedure _DoTotal is readily callable from a small-model Borland C++ program with the statement

```cpp
DoTotal();
```

Note that _DoTotal expects some other part of the program to define the external variable Repetitions. Similarly, the variable StartingValue is made public, so other portions of the program can access it. The following Borland C++ module, SHOWTOT.CPP, accesses public data in DOTOTAL.ASM and provides external data to DOTOTAL.ASM:

```cpp
#include <stdio.h>
extern "C" int DoTotal(void);
extern int StartingValue;

int Repetitions;

int main()
{
  Repetitions = 10;
  StartingValue = 2;
  printf("%d\n", DoTotal());
  return 0;
}
```
StartingValue doesn’t have to go in the Extern “C” block because variable names are not mangled.

To create the executable program SHOWTOT.EXE from SHOWTOT.CPP and DOTOTAL.ASM, enter the command line

```
bcc showtot.cpp dototal.asm
```

If you wanted to link _DoTotal to a compact-model C++ program, you would simply change the .MODEL directive to .MODEL COMPACT. If you wanted to use a far segment in DOTOTAL.ASM, you could use the .FARDATA directive.

In short, generating the correct segment ordering, memory model, and segment names for linking with Borland C++ is easy with the simplified segment directives.

**Old-style segment directives and Borland C++**

Simply put, it’s a nuisance interfacing Turbo Assembler code to C++ code using the old-style segment directives. For example, if you replace the simplified segment directives in DOTOTAL.ASM with old-style segment directives, you get

```assembly
DGROUP GROUP _DATA,_BSS
_DATA SEGMENT WORD PUBLIC 'DATA'
EXTERN _Repetitions:WORD ;externally defined
PUBLIC _StartingValue ;available to other modules
.STARTINGValue DW 0
_DATA ENDS
_BSS SEGMENT WORD PUBLIC 'BSS'
RunningTotal DW ?
_BSS ENDS
_TEXT SEGMENT BYTE PUBLIC 'CODE'
ASSUME cs:_TEXT,ds:DGROUP,ss:DGROUP
PUBLIC _DoTotal
_DoTotal PROC ;function (near-callable.
 ; in small model)
 mov cx,[_Repetitions] ;# of counts to do.
 mov ax,[_StartingValue]
 mov [RunningTotal],ax ;set initial value
TotalLoop:
 inc [RunningTotal] ;RunningTotal++
 loop TotalLoop
 mov ax,[RunningTotal] ;return final total
 ret
_DoTotal ENDP
_TEXT ENDS
END
```

The version with old-style segment directives is not only longer, but also much harder to read and harder to change to match a different C++ memory model. When you’re interfacing to Borland C++, there’s generally no advantage to using the old-style segment directives. If you still want to use the old-style segment directives when interfacing to Borland C++, you’ll have to identify the correct segments for the memory model your C++ code uses.
The easy way to determine the appropriate old-style segment directives for linking with a given Borland C++ program is to compile the main module of the Borland C++ program in the desired memory model with the -S option. This causes Borland C++ to generate an assembler version of the C++ code. In that C++ code, you'll find all the old-style segment directives used by Borland C++; just copy them into your assembler code.

You can also find out what the appropriate old-style directives are by compiling as you normally would (without the -S option) and then using TDUMP, a utility that comes with Turbo Assembler, to display all the segment definition records. Use this command line:

```
tdump -0isegdef module.obj
```

**Segment defaults: When is it necessary to load segments?**

Under some circumstances, your C++-callable assembler functions might have to load DS and/or ES in order to access data. It's also useful to know the relationships between the settings of the segment registers on a call from Borland C++, since sometimes assembler code can take advantage of the equivalence of two segment registers. Let's take a moment to examine the settings of the segment registers when an assembler function is called from Borland C++, the relationships between the segment registers, and the cases in which an assembler function might need to load one or more segment registers.

On entry to an assembler function from Borland C++, the CS and DS registers have the following settings, depending on the memory model in use (SS is always used for the stack segment, and ES is always used as a scratch segment register):

**Table 18.1** Register settings when Borland C++ enters assembler

<table>
<thead>
<tr>
<th>Model</th>
<th>CS</th>
<th>DS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tiny</td>
<td>_TEXT</td>
<td>DGROUP</td>
</tr>
<tr>
<td>Small</td>
<td>_TEXT</td>
<td>DGROUP</td>
</tr>
<tr>
<td>Compact</td>
<td>_TEXT</td>
<td>DGROUP</td>
</tr>
<tr>
<td>Medium</td>
<td>filename_TEXT</td>
<td>DGROUP</td>
</tr>
<tr>
<td>Large</td>
<td>filename_TEXT</td>
<td>DGROUP</td>
</tr>
<tr>
<td>Huge</td>
<td>filename_TEXT</td>
<td>calling_filename_DATA</td>
</tr>
</tbody>
</table>

*filename* is the name of the assembler module, and *calling_filename* is the name of the module calling the assembler module.

In the tiny model, _TEXT and DGROUP are the same, so CS equals DS on entry to functions. Also in the tiny, small, and medium models, SS equals DS on entry to functions.

So, when is it necessary to load a segment register in a C++-callable assembler function? First, you should never have to (or want to) directly load the CS or SS registers. CS is automatically set as needed on far calls, jumps, and returns, and can't be tampered with otherwise. SS always points to the stack segment, which should never change during the course of a program (unless you're writing code that switches stacks, in which case you had best know exactly what you're doing).
ES is always available for you to use as you wish. You can use ES to point at far data, or you can load ES with the destination segment for a string instruction.

That leaves the DS register; in all Borland C++ models other than the huge model, DS points to the static data segment (DGROUP) on entry to functions, and that’s generally where you’ll want to leave it. You can always use ES to access far data, although you may find it desirable to instead temporarily point DS to far data that you’re going to access intensively, thereby saving many segment override instructions in your code. For example, you could access a far segment in either of the following ways:

```assembly
.Counter DW 0
.CODE
PUBLIC _AsmFunction
_AsmFunction PROC
    mov ax,@fardata
    mov es,ax ;point ES to far data segment
    inc es: [Counter] ;increment counter variable
    ...
_AsmpFunction ENDP
```

or

```assembly
.Counter DW 0
.CODE
PUBLIC _AsmFunction
_AsmFunction PROC
    ASSUME ds:@fardata
    mov ax,@fardata
    mov ds,ax ;point DS to far data segment
    inc [Counter] ;increment counter variable
    ASSUME ds:@data
    mov ax,@data
    mov ds,ax ;point DS back to DGROUP
    ...
_AsmpFunction ENDP
```

The second version has the advantage of not requiring an ES: override on each memory access to the far data segment. If you do load DS to point to a far segment, be sure to restore it like in the preceding example before attempting to access any variables in DGROUP. Even if you don’t access DGROUP in a given assembler function, be sure to restore DS before exiting since Borland C++ assumes that functions leave DS unchanged.
Handling DS in C++-callable huge model functions is a bit different. In the huge model, Borland C++ doesn’t use **DGROUP** at all. Instead, each module has its own data segment, which is a far segment relative to all the other modules in the program; there is no commonly shared near data segment. On entry to a function in the huge model, DS should be set to point to that module’s far segment and left there for the remainder of the function, as follows:

```
:.
.FARDATA
:.
.CODE
PUBLIC_AsmFunction
_AsmFunction PROC
  push ds
  mov ax,@fardata
  mov ds,ax
  ...
  pop ds
  ret
_AsmFunction ENDP
:
```

Note that the original state of DS is preserved with a **PUSH** on entry to _AsmFunction_ and restored with a **POP** before exiting; even in the huge model, Borland C++ requires all functions to preserve DS.

**Publics and externals**
Turbo Assembler code can call C++ functions and reference external C++ variables. Borland C++ code can likewise call public Turbo Assembler functions and reference public Turbo Assembler variables. Once Borland C++-compatible segments are set up in Turbo Assembler, as described in the preceding sections, only the following few simple rules are necessary to share functions and variables between Borland C++ and Turbo Assembler.

**Underscores and the C language**
If you are programming in C or C++, all external labels should start with an underscore character (_). The C and C++ compilers automatically prefix an underscore to all function and external variable names when they’re used in C/C++ code, so you only need to attend to underscores in your assembler code. You must be sure that all assembler references to C and C++ functions and variables begin with underscores, and you must begin all assembler functions and variables that are made public and referenced by C/C++ code with underscores.

For example, the following C code (link2asm.cpp),

```c
int ToggleFlag();
int Flag;
main()
{
  ToggleFlag();
}
```
links properly with the following assembler program (CASMLINK.ASM):

```assembly
.MODEL small
.DATA
EXTRN _Flag:WORD
.CODE
PUBLIC _ToggleFlag
_TOGGLEFLAG PROC

cmp [Flag], 0 ; is the flag reset?
jz SetTheFlag ; yes, set it
mov [Flag], 0 ; no, reset it
jmp short EndToggleFlag ; done

SetTheFlag:
    mov [Flag], 1 ; set flag
EndToggleFlag:
    ret
_TOGGLEFLAG ENDP
END
```

**Note**  Labels not referenced by C code, such as SetTheFlag, don’t need leading underscores.

When you use the C language specifier in your EXTRN and PUBLIC directives, as in the following program (CSPEC.ASM),

```assembly
.MODEL small
.DATA
EXTRN C Flag:word
.CODE
PUBLIC C ToggleFlag
_TOGGLEFLAG PROC

cmp [Flag], 0
jz SetTheFlag ; yes, set it
mov [Flag], 0 ; no, reset it
jmp short EndToggleFlag ; done

SetTheFlag:
    mov [Flag], 1
EndToggleFlag:
    ret
_TOGGLEFLAG ENDP
END
```

Turbo Assembler causes the underscores to be prefixed automatically when Flag and ToggleFlag are published in the object module.

The significance of uppercase and lowercase

Turbo Assembler is normally insensitive to case when handling symbolic names, making no distinction between uppercase and lowercase letters. Since C++ is case-sensitive, it’s desirable to have Turbo Assembler be case-sensitive, at least for those symbols that are shared between assembler and C++. /ml and /mx make this possible.

The /ml command-line switch causes Turbo Assembler to become case-sensitive for all symbols. The /mx command-line switch causes Turbo Assembler to become case-sensitive for public (PUBLIC), external (EXTRN), global (GLOBAL), and communal
COMM symbols only. When Borland C++ calls Turbo Assembler, it uses the /ML switch. Most of the time you should use /ML also.

Label types
While assembler programs are free to access any variable as data of any size (8 bit, 16 bit, 32 bit, and so on), it is generally a good idea to access variables in their native size. For instance, it usually causes problems if you write a word to a byte variable:

```assembly
SmallCount DB 0
mov WORD PTR [SmallCount],0fffh
```

Consequently, it's important that your assembler EXTRN statements that declare external C++ variables specify the right size for those variables, since Turbo Assembler has only your declaration to go by when deciding what size access to generate to a C++ variable. Given the statement

```cpp
c char c
```

in a C++ program, the assembler code

```assembly
EXTRN c:WORD
inc [c]
```

could lead to problems, since every 256th time the assembler code incremented c, c would turn over. And, since c is erroneously declared as a word variable, the byte at OFFSET c + 1 is incorrectly incremented, and with unpredictable results.

Correspondence between C++ and assembler data types is as follows:

<table>
<thead>
<tr>
<th>C++ data type</th>
<th>Assembler data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned char</td>
<td>byte</td>
</tr>
<tr>
<td>char</td>
<td>byte</td>
</tr>
<tr>
<td>enum</td>
<td>word</td>
</tr>
<tr>
<td>unsigned short</td>
<td>word</td>
</tr>
<tr>
<td>short</td>
<td>word</td>
</tr>
<tr>
<td>unsigned int</td>
<td>word</td>
</tr>
<tr>
<td>int</td>
<td>word</td>
</tr>
<tr>
<td>unsigned long</td>
<td>dword</td>
</tr>
<tr>
<td>long</td>
<td>dword</td>
</tr>
<tr>
<td>float</td>
<td>dword</td>
</tr>
<tr>
<td>double</td>
<td>qword</td>
</tr>
<tr>
<td>long double</td>
<td>tbyte</td>
</tr>
<tr>
<td>near *</td>
<td>word</td>
</tr>
<tr>
<td>far *</td>
<td>dword</td>
</tr>
</tbody>
</table>
Far externals
If you’re using the simplified segment directives, EXTRN declarations of symbols in far segments must not be placed within any segment, since Turbo Assembler considers symbols declared within a given segment to be associated with that segment. This has its drawbacks: Turbo Assembler cannot check the addressability of symbols declared EXTRN outside any segment, and so can neither generate segment overrides as needed nor inform you when you attempt to access that variable when the correct segment is not loaded. Turbo Assembler still assembles the correct code for references to such external symbols, but can no longer provide the normal degree of segment addressability checking.

You can use the old-style segment directives to explicitly declare the segment each external symbol is in, and then place the EXTRN directive for that symbol inside the segment declaration. This is a lot of work, however; if you make sure that the correct segment is loaded when you access far data, it’s easiest to just put EXTRN declarations of far symbols outside all segments. For example, suppose that FILE1.ASM contains

```
.FARDATA
File1Variable DB 0
```

Then if FILE1.ASM is linked to FILE2.ASM, which contains

```
.DATA
EXTRN File1Variable:BYTE
.CODE
Start PROC
mov ax,SEG File1Variable
mov ds,ax
```

SEG File1Variable will not return the correct segment. The EXTRN directive is placed within the scope of the DATA directive of FILE2.ASM, so Turbo Assembler considers File1Variable to be in the near DATA segment of FILE2.ASM rather than in the FARDATA segment.

The following code for FILE2.ASM allows SEG File1Variable to return the correct segment:

```
.DATA
@curseg ENDS
EXTRN File1Variable:BYTE
.CODE
Start PROC
mov ax,SEG File1Variable
mov ds,ax
```

Here, the @curseg ENDS directive ends the .DATA segment, so no segment directive is in effect when File1Variable is declared external.
**Linker command line**

The simplest way to link Borland C++ modules with Turbo Assembler modules is to enter a single Borland C++ command line and let Borland C++ do all the work. Given the proper command line, Borland C++ will compile the C++ code, invoke Turbo Assembler to do the assembling, and invoke TLINK to link the object files into an executable file. Suppose, for example, that you have a program consisting of the C++ files MAIN.CPP and STAT.CPP and the assembler files SUMM.ASM and DISPLAY.ASM. The command line

\[
\text{bcc main.cpp stat.cpp summ.asm display.asm}
\]

compiles MAIN.CPP and STAT.CPP, assembles SUMM.ASM and DISPLAY.ASM, and links all four object files, along with the C++ start-up code and any required library functions, into MAIN.EXE. You only need remember the .ASM extensions when typing your assembler file names.

If you use TLINK in stand-alone mode, the object files generated by Turbo Assembler are standard object modules and are treated just like C++ object modules. See Appendix C for more information about using TLINK in stand-alone mode.

**Parameter passing**

Borland C++ passes parameters to functions on the stack. Before calling a function, Borland C++ first pushes the parameters to that function onto the stack, starting with the right-most parameter and ending with the left-most parameter. The C++ function call

\[
\text{Test(i, j, l);}
\]

compiles to

\[
\text{mov ax, l} \\
\text{push ax} \\
\text{push WORD PTR DGROUP:_j} \\
\text{push WORD PTR DGROUP:_i} \\
\text{call NEAR PTR _Test} \\
\text{add sp, 6}
\]

in which you can clearly see the right-most parameter, 1, being pushed first, then j, and finally i.

Upon return from a function, the parameters that were pushed on the stack are still there, but are no longer useful. Consequently, immediately following each function call, Borland C++ adjusts the stack pointer back to the value it contained before the parameters were pushed, thereby discarding the parameters. In the previous example, the three parameters of 2 bytes each take up 6 bytes of stack space altogether, so Borland C++ adds 6 to the stack pointer to discard the parameters after the call to Test. The important point here is that under the default C/C++ calling conventions, the calling code is responsible for discarding the parameters from the stack.
Assembler functions can access parameters passed on the stack relative to the BP register. For example, suppose the function Test in the previous example is the following assembler function, called PRMSTACK.ASM:

```
.MODEL small
.CODE
PUBLIC _Test
_Test PROC
push bp
mov bp,sp
mov ax,[bp+4] ;get parameter 1
add ax,[bp+6] ;add parameter 2 to parameter 1
sub ax,[bp+8] ;subtract parameter 3 from sum
pop bp
ret
_Test ENDP
END
```

You can see that Test is getting the parameters passed by the C++ code from the stack, relative to BP. (Remember that BP addresses the stack segment.) But just how are you to know where to find the parameters relative to BP?  

```
i = 25;
j = 4;
Test(i, j, 1);
```

The parameters to Test are at fixed locations relative to SP, starting at the stack location 2 bytes higher than the location of the return address that was pushed by the call. After loading BP with SP, you can access the parameters relative to BP. However, you must first preserve BP, since the calling C++ code expects you to return with BP unchanged. Pushing BP changes all the offsets on the stack.

```
push bp
mov bp,sp
```

This is the standard C++ stack frame, the organization of a function's parameters and automatic variables on the stack. As you can see, no matter how many parameters a C++ program might have, the left-most parameter is always stored at the stack address immediately above the pushed return address, the next parameter to the right is stored just above the left-most parameter, and so on. As long as you know the order and type of the passed parameters, you always know where to find them on the stack.

Space for automatic variables can be reserved by subtracting the required number of bytes from SP. For example, room for a 100-byte automatic array could be reserved by starting Test with

```
push bp
mov bp,sp
sub sp,100
```

Since the portion of the stack holding automatic variables is at a lower address than BP, negative offsets from BP are used to address automatic variables. For example,

```
mov BYTE PTR [bp-100], 0
```

would set the first byte of the 100-byte array you reserved earlier to zero. Passed parameters, on the other hand, are always addressed at positive offsets from BP.

While you can, if you wish, allocate space for automatic variables as shown previously, Turbo Assembler provides a special version of the LOCAL directive that makes allocation and naming of automatic variables a snap. When LOCAL is encountered within a procedure, it is assumed to define automatic variables for that procedure. For example,

```
LOCAL LocalArray:BYTE:100,LocalCount:WORD = AUTO_SIZE
```

defines the automatic variables LocalArray and LocalCount. LocalArray is actually a label equated to [BP–100], and LocalCount is actually a label equated to [BP–102], but you can use them as variable names without ever needing to know their values. AUTO_SIZE is the total number of bytes of automatic storage required; you must subtract this value from SP in order to allocate space for the automatic variables.

Here’s how you might use LOCAL:

```
  ;
  _TestSub PROC
  LOCAL LocalArray:BYTE:100,LocalCount:WORD=AUTO_SIZE
  push bp ;preserve caller's stack frame pointer
  mov bp,sp ;set up our own stack frame pointer
  sub sp,AUTO_SIZE ;allocate room for automatic variables
  mov [LocalCount],10 ;set local count variable to 10
  ; (LocalCount is actually [BP-102])
  ;
  mov cx,[LocalCount] ;get count from local variable
  mov al,'A' ;we'll fill with character 'A'
  lea bx, [LocalArray] ;point to local array
  ; (LocalArray is actually [BP-100])

FillLoop:
  mov [bx],al ;fill next byte
  inc bx ;point to following byte
  loop FillLoop ;do next byte, if any

mov sp,bp ;deallocate storage for automatic
; variables (add sp,AUTO_SIZE would
; also have worked)
pop bp ;restore caller's stack frame pointer
ret
_TestSub ENDP
```

In this example, note that the first field after the definition of a given automatic variable is the data type of the variable: BYTE, WORD, DWORD, NEAR, and so on. The second field after the definition of a given automatic variable is the number of elements of that variable’s type to reserve for that variable. This field is optional and defines an automatic array if used; if it is omitted, one element of the specified type is reserved.
Consequently, *LocalArray* consists of 100 byte-sized elements, while *LocalCount* consists of 1 word-sized element.

Also note that the **LOCAL** line in the preceding example ends with =**AUTO_SIZE**. This field, beginning with an equal sign, is optional; if present, it sets the label following the equal sign to the number of bytes of automatic storage required. You must then use that label to allocate and deallocate storage for automatic variables, since the **LOCAL** directive only generates labels, and doesn't actually generate any code or data storage. To put this another way: **LOCAL** doesn't allocate automatic variables, but simply generates labels that you can readily use to both allocate automatic storage for and access automatic variables.

As you can see, **LOCAL** makes it much easier to define and use automatic variables. Note that the **LOCAL** directive has a completely different meaning when used in macros.

By the way, Borland C++ handles stack frames in just the way we've described here. You might find it instructive to compile a few Borland C++ modules with the -S option, and then look at the assembler code Borland C++ generates to see how Borland C++ creates and uses stack frames.

This looks good so far, but there are further complications. First of all, this business of accessing parameters at constant offsets from BP is a nuisance; not only is it easy to make mistakes, but if you add another parameter, all the other stack frame offsets in the function must be changed. For example, suppose you change *Test* to accept four parameters:

```c
Test(Flag, i, j, k);
```

Suddenly *i* is at offset 6, not offset 4, *j* is at offset 8, not offset 6, and so on. You can use equates for the parameter offsets:

```c
:
Flag       EQU 4
AddParm1   EQU 6
AddParm2   EQU 8
SubParm1   EQU 10
mov  ax, [bp+AddParm1]
add  ax, [bp+AddParm2]
sub  ax, [bp+SubParm1]
:
```

but it's still a nuisance to calculate the offsets and maintain them. There's a more serious problem, too: The size of the pushed return address grows by 2 bytes in far code models, as do the sizes of passed code pointers and data pointer in far code and far data models, respectively. Writing a function that can be easily assembled to access the stack frame properly in any memory model would thus seem to be a difficult task.

Turbo Assembler, however, provides you with the **ARG** directive, which makes it easy to handle passed parameters in your assembler routines.
The ARG directive automatically generates the correct stack offsets for the variables you specify. For example,

```
arg FillArray:WORD,Count:WORD,FillValue:BYTE
```
specifies three parameters: FillArray, a word-sized parameter; Count, a word-sized parameter, and FillValue, a byte-sized parameter. ARG actually sets the label FillArray to [BP+4] (assuming the example code resides in a near procedure), the label Count to [BP+6], and the label FillValue to [BP+8]. However, ARG is valuable precisely because you can use ARG-defined labels without ever knowing the values they're set to.

For example, suppose you've got a function FillSub, called from C++ as follows:

```c
extern "C" {
void FillSub(
    char *FillArray,
    int Count,
    char FillValue);
}
main()
{
const int ARRAY_LENGTH=100;
char TestArray[ARRAY_LENGTH];
    FillSub(TestArray,ARRAY_LENGTH,'*');
}
```
You could use ARG in FillSub to handle the parameters as follows:

```
_FILLSub PROC NEAR
ARG FillArray:WORD,Count:WORD,FillValue:BYTE
push bp                   ;preserve caller's stack frame
mov bp,sp                 ;set our own stack frame
mov bx,[FillArray]        ;get pointer to array to fill
mov cx,[Count]            ;get length to fill
mov al,[FillValue]        ;get value to fill with
FillLoop:                 
    mov [bx],al            ;fill a character
    inc bx                 ;point to next character
    loop FillLoop          ;do next character
    pop bp                 ;restore caller's stack frame
ret
_FILLSub ENDP
```
That's really all it takes to handle passed parameters with ARG. Better yet, ARG automatically accounts for the different sizes of near and far returns.

**Preserving registers**

As far as Borland C++ is concerned, C++-callable assembler functions can do anything as long as they preserve the following registers: BP, SP, CS, DS, and SS. While these registers can be altered during the course of an assembler function, when the calling code is returned, they must be exactly as they were when the assembler function was called. AX, BX, CX, DX, ES, and the flags can be changed in any way.
SI and DI are special cases, since they’re used by Borland C++ as register variables. If register variables are enabled in the C++ module calling your assembler function, you must preserve SI and DI; but if register variables are not enabled, SI and DI need not be preserved.

It’s good practice to always preserve SI and DI in your C++-callable assembler functions, regardless of whether register variables are enabled. You never know when you might link a given assembler module to a different C++ module, or recompile your C++ code with register variables enabled, without remembering that your assembler code needs to be changed as well.

Returning values

A C++-callable assembler function can return a value, just like a C++ function. Function values are returned as follows:

<table>
<thead>
<tr>
<th>Return value type</th>
<th>Return value location</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned char</td>
<td>AX</td>
</tr>
<tr>
<td>char</td>
<td>AX</td>
</tr>
<tr>
<td>enum</td>
<td>AX</td>
</tr>
<tr>
<td>unsigned short</td>
<td>AX</td>
</tr>
<tr>
<td>short</td>
<td>AX</td>
</tr>
<tr>
<td>unsigned int</td>
<td>AX</td>
</tr>
<tr>
<td>int</td>
<td>AX</td>
</tr>
<tr>
<td>unsigned long</td>
<td>DX:AX</td>
</tr>
<tr>
<td>long</td>
<td>DX:AX</td>
</tr>
<tr>
<td>float</td>
<td>8087 top-of-stack (TOS) register (ST(0))</td>
</tr>
<tr>
<td>double</td>
<td>8087 top-of-stack (TOS) register (ST(0))</td>
</tr>
<tr>
<td>long double</td>
<td>8087 top-of-stack (TOS) register (ST(0))</td>
</tr>
<tr>
<td>near *</td>
<td>AX</td>
</tr>
<tr>
<td>far *</td>
<td>DX:AX</td>
</tr>
</tbody>
</table>

In general, 8- and 16-bit values are returned in AX, and 32-bit values are returned in DX:AX, with the high 16 bits of the value in DX. Floating-point values are returned in ST(0), which is the 8087’s top-of-stack (TOS) register, or in the 8087 emulator’s TOS register if the floating-point emulator is being used.

Structures are a bit more complex. Structures that are 1 or 2 bytes in length are returned in AX, and structures that are 4 bytes in length are returned in DX:AX. When a function that returns a three-byte structure or a structure larger than 4 bytes is called, the caller must allocate space for the return value (usually on the stack), and pass the address of this space to the function as an additional “hidden” parameter. The function assigns the return value through this pointer argument, and returns that pointer as its result. As with all pointers, near pointers to structures are returned in AX, and far pointers to structures are returned in DX:AX.
Let's look at a small model C++-callable assembler function, `FindLastChar`, that returns a near pointer to the last character of a passed string. The C++ prototype for this function would be

```cpp
extern char * FindLastChar(char * StringToScan);
```

where `StringToScan` is the non-empty string for which a pointer to the last character is to be returned.

Here's `FindLastChar`, from FINDCHAR.ASM:

```asm
.MODEL small
.CODE
PUBLIC _FindLastChar
_FindLastChar PROC
ARG StringToScan:WORD
push bp
mov bp, sp
clid ;we need string instructions to count up
mov ax,ds
mov es,ax ;set ES to point to the near data segment
mov di, [StringToScan] ;point ES:DI to start of passed string
mov al,0 ;search for the null that ends the string
mov cx,0ffffh ;search up to 64K-1 bytes
reptz scasb ;look for the null
dec di ;point back to the null
dec di ;point back to the last character
mov ax,di ;return the near pointer in AX
pop bp
ret
_FindLastChar ENDP
END
```

The final result, the near pointer to the last character in the passed string, is returned in AX.

**Calling an assembler function from C++**

Now look at an example of Borland C++ code calling a Turbo Assembler function. The following Turbo Assembler module, COUNT.ASM, contains the function `LineCount`, which returns counts of the number of lines and characters in a passed string:

```asm
; Small model C++-callable assembler function to count the number of lines and characters in a zero-terminated string.

; Function prototype:
; extern unsigned int LineCount(char * near StringToCount,
; unsigned int near * CharacterCountPtr);
; Input:
; char near * StringToCount: pointer to the string on which a line count is to be performed
```
unsigned int near * CharacterCountPtr: pointer to the
int variable in which the character count is
to be stored

NEWLINE EQU 0ah ;the linefeed character is C's
            ; newline character

.MODEL small
.CODE
PUBLIC _LineCount
_LineCount PROC
push bp
mov bp, sp
push si ;preserve calling program's
        ; register variable, if any
mov si,[bp+4] ;point SI to the string
sub cx,cx ;set character count to 0
mov dx,cx ;set line count to 0
LineCountLoop:
    lodsb ;get the next character
    and al,al ;is it null, to end the string?
    jz EndLineCount ;yes, we're done
    inc cx ;no, count another character
    cmp al,NEWLINE ;is it a newline?
    jnz LineCountLoop ;no, check the next character
    inc dx ;yes, count another line
    jmp LineCountLoop
EndLineCount:
    inc dx ;count the line that ends with the
            ; null character
    mov bx,[bp+6] ;point to the location at which to
                 ; return the character count
    mov [bx],cx ;set the character count variable
    mov ax,dx ;return line count as function value
    pop si ;return line count as function value
    ;variable, if any
    pop bp
    ret
_LineCount ENDP
END

The following C++ module, CALLCT.CPP, is a sample invocation of the LineCount function:

#include <stdio.h>
char * TestString="Line 1
line 2
line3";
extern "C" unsigned int LineCount(char * StringToCount,

unsigned int * CharacterCountPtr);

int main()
{
    unsigned int LCount;
    unsigned int CCount;
    LCount = LineCount(TestString, &CCount);
printf("Lines: %d\nCharacters: %d\n", LCount, CCount);
return 0;
}

The two modules are compiled and linked together with the command line

bcc -ms callct.cpp count.asm

As shown here, LineCount will work only when linked to small-model C++ programs since pointer sizes and locations on the stack frame change in other models. Here's a version of LineCount, COUNTLG.ASM, that will work with large-model C++ programs (but not small-model ones, unless far pointers are passed, and LineCount is declared far):

; Large model C++-callable assembler function to count the number
; of lines and characters in a zero-terminated string.
;
; Function prototype:
;
extern unsigned int LineCount(char * far StringToCount,
    unsigned int * far CharacterCountPtr);
char far * StringToCount: pointer to the string on which
    a line count is to be performed
;
unsigned int far * CharacterCountPtr: pointer to the
    int variable in which the character count
    is to be stored
;
NEWLINE EQU Oah ; the linefeed character is C's newline
    ; character

.MODEL large
.CODE
PUBLIC _LineCount
_LineCount PROC
  push bp
  mov bp,sp
  push si
    ; preserve calling program's
    ; register variable, if any
  push ds
    ; preserve C's standard data seg
  lds si,[bp+6]
    ; point DS:SI to the string
  sub cx,cx
    ; set character count to 0
  mov dx,cx
    ; set line count to 0
LineCountLoop:
  lodsb
    ; get the next character
  and al,al
    ; is it null, to end the string?
  jz EndLineCount
    ; yes, we're done
  inc cx
    ; no, count another character
  cmp al,NEWLINE
    ; is it a newline?
  jnz LineCountLoop
    ; no, check the next character
  inc dx
    ; yes, count another line
  jmp LineCountLoop
EndLineCount:
  inc dx
    ; count line ending with null
    ; character
  les bx,[bp+10]
    ; point ES:BX to the location at
    ; which to return char count

Chapter 18, Interfacing Turbo Assembler with Borland C++ 217
Writing C++ member functions in assembly language

While you can write a member function of a C++ class completely in assembly language, it is not easy. For example, all member functions of C++ classes are name-mangled to provide the type-safe linkage that makes things like overridden functions available, and your assembler function would have to know exactly what name C++ would be expecting for the member function. To access the member variables you must prepare a STRUC definition in your assembler code that defines all the member variables with exactly the same sizes and locations. If your class is a derived class, there may be other member variables derived from a base class. Even if your class is not a descendant of another class, the location of member variables in memory changes if the class includes any virtual functions.

If you write your function using inline assembler, Borland C++ can take care of these issues for you. But if you must write your function in assembly language, (perhaps because you are reusing some existing assembler code), there are some special techniques you can use to make things easier.

Create a dummy stub C++ function definition for the assembler function. This stub will satisfy the linker because it will have a properly mangled name for the member function. The dummy stub then calls your assembler function and passes to it the member variables and other parameters. Since your assembler code has all the parameters it needs passed as arguments, you don’t have to worry about changes in the class definition. Your assembler function can be declared in the C++ code as an extern “C” function, just as we have shown you in other examples.

Note For an example of how to write assembly functions using mangled names, see the example on page 199.

Here’s an example, called COUNTER.CPP:

```c
#include <stdio.h>

class counter {
    // Private member variables:
    int count; // The ongoing count

    public:
        counter(void){ count=0; }
        int get_count(void){return count;}
```
// Two functions that will actually be written
// in assembler:
void increment(void);
void add(int what_to_add=-1);
// Note that the default value only
// affects calls to add, it does not
// affect the code for add.
);

extern "C" { 
// To create some unique, meaningful names for the
// assembler routines, prepend the name of the class
// to the assembler routine. Unlike some assemblers,
// Turbo Assembler has no problem with long names.
void counter_increment(int *count); // We will pass a
// pointer to the
// count variable.
// Assembler will
// do the incrementing.
void counter_add(int *count, int what_to_add);
}

void counter::increment(void) {
    counter_increment(&count);
}

void counter::add(int what_to_add) {
    counter_add(&count, what_to_add);
}

int main() {
    counter Counter;
    printf("Before count: \%d\n", Counter.get_count());
    Counter.increment();
    Counter.add(5);
    printf("After count: \%d\n", Counter.get_count());
    return 0;
}

Your assembler module that defines the count_add_increment and count_add_add
routines could look like this example, called COUNTADD.ASM:

MODEL small ; Select small model (near code and data)
.CODE
PUBLIC _counter_increment
_counter_increment PROC
ARG count_offset:word ; Address of the member variable
push bp ; Preserve caller's stack frame
mov bp,sp ; Set our own stack frame
mov bx,[count_offset] ; Load pointer
inc word ptr [bx] ; Increment member variable
pop bp ; Restore caller's stack frame
ret
_counter_increment ENDP
Using this method, you don’t have to worry about changes in your class definition. Even if you add or delete member variables, make this class a derived class, or add virtual functions, you won’t have to change your assembler module. You need to reassemble your module only if you change the structure of the count member variable, or if you make a large model version of this class. You need to reassemble because you have to deal with a segment and an offset when referring to the count member variable.

Pascal calling conventions

So far, you’ve seen how C++ normally passes parameters to functions by having the calling code push parameters right to left, call the function, and discard the parameters from the stack after the call. Borland C++ is also capable of following the conventions used by Pascal programs in which parameters are passed from left to right, and the called function discards the parameters from the stack. In Borland C++, Pascal conventions are enabled with the -p command-line option or the pascal keyword.

The following example, ASMPSCLC.ASM, shows an assembler function that uses Pascal conventions:

```assembly
; Called as: TEST_PROC(i, j, k);

i equ 8 ;leftmost parameter
j equ 6 ;rightmost parameter
k equ 4

.MODEL small
.CODE
PUBLIC TEST_PROC

TEST_PROC PROC
push bp
mov bp,sp
mov ax,[bp+i] ;get i
add ax,[bp+j] ;add j to i
sub ax,[bp+k] ;subtract k from the sum

TEST_PROC ENDP
END
```
Note that RET 6 is used by the called function to clear the passed parameters from the stack.

Pascal calling conventions also require all external and public symbols to be in uppercase, with no leading underscores. Why would you want to use Pascal calling conventions in a C++ program? Code that uses Pascal conventions tends to be somewhat smaller and faster than normal C++ code since there’s no need to execute an ADD SP n instruction to discard the parameters after each call.

Calling Borland C++ from Turbo Assembler

Although it’s most common to call assembler functions from C++ to perform specialized tasks, you might occasionally want to call C++ functions from assembler. As it turns out, it’s actually easier to call a Borland C++ function from a Turbo Assembler function than the reverse since no stack-frame handling on the part of the assembler code is required. Let’s take a quick look at the requirements for calling Borland C++ functions from assembler.

Link in the C++ startup code

As a general rule, you should only call Borland C++ library functions from assembler code in programs that link in the C++ startup module as the first module linked.

Note Generally, you should not call Borland C++ library functions from programs that don’t link in the C++ startup module since some Borland C++ library functions will not operate properly if the startup code is not linked in. If you really want to call Borland C++ library functions from such programs, we suggest you look at the startup source code (the file C0.ASM on the Borland C++ distribution disks) and purchase the C++ library source code from Borland. This way, you can be sure to provide the proper initialization for the library functions you need.

Note Calling user-defined C++ functions that in turn call C++ library functions falls into the same category as calling library functions directly; lack of the C++ startup can potentially cause problems for any assembler program that calls C++ library functions, directly or indirectly.

The segment setup

As we learned earlier, you must make sure that Borland C++ and Turbo Assembler are using the same memory model and that the segments you use in Turbo Assembler match those used by Borland C++.

Turbo Assembler has a tchuge memory model that supports Borland C++’s huge memory model. Refer to the previous section if you need a refresher on matching memory models and segments. Also, remember to put EXTRN directives for far symbols either outside all segments or inside the correct segment.
Performing the call

All you need to do when passing parameters to a Borland C++ function is push the right-most parameter first, then the next right-most parameter, and so on, until the left-most parameter has been pushed. Then just call the function. For example, when programming in Borland C++, to call the Borland C++ library function `strcpy` to copy `SourceString` to `DestString`, you would type:

```c
strcpy(DestString, SourceString);
```

To perform the same call in assembler, you would use:

```
lea ax, SourceString ; rightmost parameter
lea bx, DestString  ; leftmost parameter
push ax             ; push rightmost first
push bx             ; push leftmost next
call _strcpy         ; copy the string
add sp, 4           ; discard the parameters
```

Don't forget to discard the parameters by adjusting SP after the call.

You can simplify your code and make it language independent at the same time by taking advantage of Turbo Assembler's CALL instruction extension:

```
call destination [language [,arg1] ...]
```

where `language` is C, CPP, PASCAL, BASIC, FORTRAN, PROLOG or NOLANGUAGE, and `arg` is any valid argument to the routine that can be directly pushed onto the processor stack.

Using this feature, the preceding code can be reduced to:

```
lea ax, SourceString
lea bx, DestString
call strcpy c,bx,ax.
```

Turbo Assembler automatically inserts instructions to push the arguments in the correct order for C++ (AX first, then BX), performs the call to `_strcpy` (Turbo Assembler automatically inserts an underscore in front of the name for C++), and cleans up the stack after the call.

If you're calling a C++ function that uses Pascal calling conventions, you have to push the parameters left to right and not adjust SP afterward:

```
lea bx, DestString  ; leftmost parameter
lea ax, SourceString ; rightmost parameter
push bx             ; push leftmost first
push ax             ; push rightmost next
call STRCPY         ; copy the string
                  ; leave the stack alone
```

Again, you can use Turbo Assembler's CALL instruction extension to simplify your code:

```
lea bx, DestString  ; leftmost parameter
lea ax, SourceString ; rightmost parameter
call strcpy pascal,bx,ax
```
Turbo Assembler automatically inserts instructions to push the arguments in the correct order for Pascal (BX first, then AX) and performs the call to STRCPY (converting the name to all uppercase, as is the Pascal convention).

The last example assumes that you’ve recompiled strcpy with the -p switch, since the standard library version of strcpy uses C++ rather than Pascal calling conventions.

Rely on C++ functions to preserve the following registers and only the following registers: SI, DI, BP, DS, SS, SP, and CS. Registers AX, BX, CX, DX, ES, and the flags may be changed arbitrarily.

### Calling a Borland C++ function from Turbo Assembler

One case in which you may wish to call a Borland C++ function from Turbo Assembler is when you need to perform complex calculations. This is especially true when mixed integer and floating-point calculations are involved; while it’s certainly possible to perform such operations in assembler, it’s simpler to let C++ handle the details of type conversion and floating-point arithmetic.

Let’s look at an example of assembler code that calls a Borland C++ function in order to get a floating-point calculation performed. In fact, let’s look at an example in which a Borland C++ function passes a series of integer numbers to a Turbo Assembler function, which sums the numbers and in turn calls another Borland C++ function to perform the floating-point calculation of the average value of the series.

The C++ portion of the program in CALCAVG.CPP is

```c
#include <stdio.h>

extern "C" float Average(int far * ValuePtr, int NumberOfValues);

#define NUMBER_OF_TEST_VALUES 10

int TestValues[NUMBER_OF_TEST_VALUES] = {
    1, 2, 3, 4, 5, 6, 7, 8, 9, 10
};

int main()
{
    printf("The average value is: %f\n",
            Average(TestValues, NUMBER_OF_TEST_VALUES));
    return 0;
}

extern "C"

float IntDivide(int Dividend, int Divisor)
{
    return (float) Dividend / (float) Divisor;
}
```

and the assembler portion of the program in AVERAGE.ASM is

```asm

; Borland C++-callable small-model function that returns the average
; of a set of integer values. Calls the Borland C++ function
; IntDivide() to perform the final division.
```
Function prototype:

```c
extern float Average(int far * ValuePtr, int NumberOfValues);
```

Input:

```c
int far * ValuePtr: ; the array of values to average
int NumberOfValues: ; the number of values to average
```

The C++ main function passes a pointer to the array of integers `TestValues` and the length of the array to the assembler function `Average`. `Average` sums the integers, then passes the sum and the number of values to the C++ function `IntDivide`. `IntDivide` casts the sum and number of values to floating-point numbers and calculates the average value, doing in a single line of C++ code what would have taken several assembler lines. `IntDivide` returns the average to `Average` in the 8087 TOS register, and `Average` just leaves the average in the TOS register and returns to `main`.

CALCAVG.CPP and AVERAGE.ASM could be compiled and linked into the executable program CALCAVG.EXE with the command

```
bcc calcavg.cpp average.asm
```

Note that `Average` will handle both small and large data models without the need for any code change since a far pointer is passed in all models. All that would be needed to support large code models (huge, large, and medium) would be use of the appropriate `.MODEL` directive.

Taking full advantage of Turbo Assembler’s language-independent extensions, the assembly code in the previous example could be written more concisely as shown here in CONCISE.ASM:
.MODEL small,C
EXTRN C IntDivide:PROC
.CODE
PUBLIC C Average
Average PROC C ValuePtr:DWORD,NumberOfValues:WORD
les bx,ValuePtr
mov cx,NumberOfValues
mov ax,0
AverageLoop:
add ax,es:[bx] ;point to the next value
add bx,2
loop AverageLoop
call IntDivide C,ax,NumberOfValues
ret
Average ENDP
END
Program blueprints

This appendix describes basic program construction information depending on specific memory models and executable object formats.

Simplified segmentation segment description

The following tables show the default segment attributes for each memory model.

Table A.1  Default segments and types for TINY memory model

<table>
<thead>
<tr>
<th>Directive</th>
<th>Name</th>
<th>Align</th>

</table>

1. STACK not assumed to be in DGROUP if FARSTACK specified in the MODEL directive.
### DOS programs

Programs designed to be executed under DOS are stored in two formats:

- **EXE format** (for EXEcutable)
- **COM format** (for COre iMage)

EXE format permits the most general program segmentation under DOS. A program can have multiple segments, and can reference segment and group names symbolically. EXE programs are thus permitted to exceed 64K in size.

COM format is essentially a throwback to a simpler era. Programs using COM format can’t contain symbolic references to group and segment names. Thus, COM programs are written using the TINY model, and are limited to 64K of code and data.

To build DOS programs, you need to use a DOS linker (like TLINK) and a program construction utility (like MAKE).

### DOS EXE program blueprint

When you load an EXE program, the operating system sets up the registers as follows:

<table>
<thead>
<tr>
<th>Register</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DS, ES</td>
<td>Contains the paragraph address of the program segment prefix (PSP) for the program. The PSP contains arguments passed to the program from the command line, and a pointer to the environment string for the program.</td>
</tr>
<tr>
<td>CS:IP</td>
<td>Contains the starting address specified by END in one of the program’s modules, or the address of the STARTUPCODE directive.</td>
</tr>
<tr>
<td>SS:SP</td>
<td>Contains the address of the last word that the stack segment specified in the program.</td>
</tr>
</tbody>
</table>

You can define EXE programs with any memory model. You should use the simplest memory model possible because it makes programming simpler and faster. For example, if you never expect your program to use more than 64K of code, data, and stack space, the TINY model would be the appropriate model to use.

The **STARTUPCODE** directive in a module emits instructions that automatically initialize all necessary registers to conform with the selected model. However, it preserves the paragraph address of the PSP in ES for the program’s use.
When you load an EXE program, the operating system allocates all remaining memory to it until the program exits. For programs that don’t use a heap, or programs that build their own heaps in this memory, this behavior is fine. Other programs can allocate memory from DOS. In this case, the memory must be freed back to DOS before you can request it from DOS.

To exit from an EXE program, use the EXITCODE directive.

Note EXEPROG.ASM, on your example Turbo Assembler disks, illustrates these topics.

Use the MAKE utility to build the EXE program. The file MAKEFILE should include all modules link with the program, as follows:

    EXEPROG.EXE: EXEPROG.OBJ
    TLINK EXEPROG;
    EXEPROG.OBJ: EXEPROG.ASM
    TASM EXEPROG

**COM program blueprint**

COM programs are restricted versions of EXE programs. You can represent every COM program as an EXE program, but not every EXE program as a COM program. The following restrictions apply:

- A COM program should be written using the TINY memory model.
- You can’t have a predefined stack segment for COM programs.
- A COM program can’t contain any direct segment or group address references. This means that the program can’t contain any direct far calls, nor can it reference any segments by name. All procedures in a COM program must be declared NEAR.
- Execution must begin at offset 100h in the code segment. To let this happen, make the first instruction in the code segment the STARTUPCODE directive.

Turbo Assembler loads a COM program starting at offset 100h of the program segment prefix (PSP). The STARTUPCODE directive for the TINY model automatically places an ORG 100h in the program to compensate for this action.

When you load a COM program, the following registers are set:

<table>
<thead>
<tr>
<th>Register</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CS,DS,ES,SS</td>
<td>Contains the paragraph address of the PSP and the program.</td>
</tr>
<tr>
<td>IP</td>
<td>Set to 100h.</td>
</tr>
<tr>
<td>SP</td>
<td>Set to 0FFFFh (the last word in the program segment).</td>
</tr>
</tbody>
</table>

If you don’t want to place the stack at the end of the program segment, you must set up a new stack. Use the uninitialized data segment (UDATASEG) for this stack.

Even though COM programs must be defined with the TINY memory model, you should still separate code, data, and uninitialized data using CODESEG, DATASEG, and UDATASEG.
Use the **EXITCODE** directive exit from a COM program the same way you exit from an EXE program.

As with EXE programs, when you load a COM program, Turbo Assembler allocates all remaining memory to it until it exits. If memory is freed back to DOS, make sure that no uninitialized data is unintentionally freed.

**Note**

COMPROG.ASM, on your example Turbo Assembler disks, illustrates these points.

Use the **MAKE** utility to build the COM program. The file **MAKEFILE** should include all modules link with the program, as follows:

```plaintext
COMPROG.COM: COMPROG.OBJ
    TLINK /t COMPROG;
COMPROG.OBJ: COMPROG.ASM
    TASM COMPROG
```

### Windows programs

Turbo Assembler can also be used to create Windows applications. Windows can run in either real mode (on all 8086 processors) or protected mode (on 80286 and higher processors). Thus, programs written for Windows can run in protected mode. You should carefully separate code and data using the **CODESEG**, **DATASEG**, and **UDATASEG** directives, and use the **WARN PRO** directive to flag any access problems that could occur at assembly time. Finally, protected mode programs should not attempt to set segment registers to calculated paragraph segment values. Segment values in protected mode are not paragraph addresses, but rather descriptors that have no meaning to an application program.

Although all the tools you need to write Windows programs are contained in your Turbo Assembler package, you might find it useful to use other language tools (such as Borland C++ or Borland Delphi) to help you effectively create Windows applications.

This appendix provides the simplest of blueprints for Windows applications and Dynamic Link Libraries (DLLs). For a more complete description of Windows applications, refer to your compiler manuals, or the appropriate Microsoft documentation.

### Windows DLL blueprint

A Dynamic Link Library (DLL) is a group of procedures that you can call from any Windows application. DLLs extend the Windows application interface.

DLLs perform many functions; for example, you can convert non-interactive DOS programs to DLLs. Support can be added for new sorts of screen entities by writing a DLL.

You can find an example program called **DLLWIN.ASM** that illustrates how to write a DLL in assembler. This assembler project is located in the **EXAMPLES\USRGUIDE\DLLWIN** directory off the main TASM subdirectory.
You can use the MAKE utility to build the DLL. DLLWIN.MAK is provided in the DLLWIN subdirectory:

```bash
dllwin.exe: dllwin.obj dllwin.def
  TLINK /v /Twd /s dllwin, dllwin, dllwin,,dllwin

dllwin.obj: dllwin.asm
  TASM /Zi dllwin,,
```

This build process requires the following linker definitions file, DLLWIN.DEF:

```plaintext
LIBRARY DLLWIN
DESCRIPTION 'Simple Assembly Windows DLL'
CODE PRELOAD MOVEABLE DISCARDABLE
DATA PRELOAD MOVEABLE SINGLE
EXETYPE WINDOWS
HEAPSIZE 4096
```

;Define imported functions. (Not necessary if you link with an
;import library like IMPORT.LIB or LIBW.LIB.)

```plaintext
IMPORTS GDI.GETWINDOWEXTEX
```

---

### Windows 16-bit application blueprint

A Windows application is very much like a DLL, except that only a single procedure is called: WinMain. Windows calls WinMain to start the procedure. The application usually has a standard structure, which lets it communicate with the Windows graphical environment.

ASMWIN.ASM, located in the EXAMPLES\USRGUIDE\ASMWIN directory off the main TASM subdirectory, shows an assembly-based Windows program.

Use the MAKE utility to build the Windows application. The file ASMWIN.MAK includes all modules to be linked in with the application:

```bash
asmwin.exe: asmwin.obj asmwin.def
  TLINK /v /Twe /s ASMWIN, ASMWIN, ASMWIN,,ASMWIN

asmwin.obj: asmwin.asm
  TASM /Zi ASMWIN,,
```

This build process requires the linker definitions file ASMWIN.DEF, which is very similar to the .DEF module used in the preceding example that generates a Windows DLL using assembly code.

A complete 16-bit Windows program is supplied in the EXAMPLES\WAP subdirectory off your main TASM directory.

### Windows 32-bit application blueprint

In high-level languages like C, C++, and Pascal, Windows 32-bit programs are almost identical to their 16-bit counterparts because the compiler handles most of the
differences. However, you must deal directly with those differences at the assembly language level. In particular, you must pay attention to the following details:

- All values pushed on the stack must be 32 bits.
- The parameters to `WndProc` must all be 32 bits.
- The EBX, ESI and EDI registers must be preserved in a Win32 callback function.
- Many of the Win32 constants are now 32 bits wide as opposed to Windows 16-bit wide constants.
- Because of Unicode support, there are both ANSI and WIDE CHAR versions of all the API functions that use strings. The ANSI version of these functions end with a capital 'A' and the WIDE CHAR versions end with a capital 'W'; no versions of these functions exist that don't end with either an 'A' or 'W.' Because of this, you must use either `TextOutA` or `TextOutW` to get the functionality of `TextOut`.

Use the following assembler and linker commands to compile a 32-bit Windows program:

```
TASM32 /zi /ml filename.asm
TLINK32 /v filename.obj, filename.exe, filename.map, import32.lib, filename.def
```

The .DEF file for the project should resemble the following:

```
NAME DESCRIPTION CODE DATA EXETYPE STACKSIZE EXPORTS
MODNAME 'Description of this module' PRELOAD MOVEABLE DISCARDABLE PRELOAD MOVEABLE MULTIPLE WINDOWS 8192 WndProc
```

A complete 32-bit Windows program is supplied in the `\EXAMPLES\WAP32` subdirectory off your main TASM directory.

**OS/2 programs**

Programs designed to be executed under the OS/2 operating system can use one of several formats, depending on the capabilities you want. OS/2 can execute programs designed for DOS program formats, as well as programs and DLLs written for Windows. However, the most powerful format available under OS/2 is the linear executable format, in which a program no longer has to manipulate segment registers, and 512 megabytes of virtual memory is available. This format is also known as flat model.

**OS/2 flat-model program blueprint**

Turbo Assembler assumes that all 32-bit segments in a flat-model program belong to a supergroup called FLAT, and share the same segment selector. (Segments that are 16-bit are allowed, but are of little use.)
When you execute a flat-model program, Turbo Assembler initializes the registers as follows:

<table>
<thead>
<tr>
<th>Register</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CS,DS,ES,SS</td>
<td>Contains the segment selector of the 32-bit linear address for the program. These registers should never have to be changed.</td>
</tr>
<tr>
<td>CS:EIP</td>
<td>Contains the address of the STARTUPCODE directive.</td>
</tr>
<tr>
<td>SS:ESP</td>
<td>Contains the address of the last word of the stack segment, which the STACK directive specifies.</td>
</tr>
<tr>
<td>FS,GS</td>
<td>Contain special values that the application should not modify.</td>
</tr>
</tbody>
</table>

You must define linear-executable programs with the FLAT model. This instructs Turbo Assembler to consider all 32-bit segments and groups to be a member of FLAT supergroup. You can also optionally specify the OS/2 operating system, which allows the STARTUPCODE and EXITCODE directives to function correctly (for example, MODEL OS2 FLAT).

The STARTUPCODE directive produces instructions that automatically initialize all necessary registers to conform to FLAT model. Similarly, the EXITCODE directive produces instructions that automatically return control to the operating system, while letting you specify an optional return value.
Turbo Assembler syntax summary

This appendix describes the syntax of Turbo Assembler expressions in a modified Backus-Naur form (BNF). The symbol ::= describes a syntactical production. Ellipses (...) indicate that an element is repeated as many times as it is found. This appendix also discusses keywords and their precedences.

Lexical grammar

valid_line ::=  
white_space valid_line  
punctuation valid_line  
number_string valid_line  
id_string valid_line  
null

white_space ::=  
space_char white_space  
space_char

space_char ::=  
All control characters, character > 128, ‘’

id_string ::=  
id_char id_string2

id_string2 ::=  
id_chr2 id_string2  
null

id_char ::=  
Any of $, %, _, ?, or any alphabetic characters
id_chr2 ::= 
id_chars plus numerics

number_string ::= 
num_string
str_string

num_string ::= 
digits alphanums
digits '.' digits exp
digits exp

;Only MASM mode DD, DQ, or DT

digits ::= 
digit digits
digit

digit ::= 
0 through 9

alphanums ::= 
digit alphanum
alpha alphanum
null

alpha ::= 
alphabetic characters

exp ::= 
E + digits
E – digits
E digits
null

str_string ::= 
Quoted string, quote enterable by two quotes in a row

punctuation ::= 
Everything that is not a space_char, id_char, ‘’ ‘’ ‘’ or digits

The period (.) character is handled differently in MASM mode and Ideal mode. This character is not required in floating-point numbers in MASM mode and also can’t be part of a symbol name in Ideal mode. In MASM mode, it is sometimes the start of a symbol name and sometimes a punctuation character used as the structure member selector.

Here are the rules for the period (.) character:

1 In Ideal mode, it’s always treated as punctuation.

2 In MASM mode, it’s treated as the first character of an ID in the following cases:
   - When it is the first character on the line, or in other special cases like EXTRN and PUBLIC symbols, it gets attached to the following symbol if the character that follows it is an id_chr2, as defined in the previous rules.
• If it appears other than as the first character on the line, or if the resulting symbol 
would make a defined symbol, the period gets appended to the start of the symbol 
following it.

MASM mode expression grammar

Expression parsing starts at MASM_expr.

MASM_expr ::=  
mexpr1

mexpr1 ::=  
SHORT mexpr1  
.TYPE mexpr1  
SMALL mexpr1 ;If 386  
LARGE mexpr1 ;If 386  
expr2

expr2 ::=

THIS itype 
symbol 
( pointer ) 
[ pointer ]

mexpr10 ::= 
mexpr11 PTR mexpr10 
mexpr11 
  TYPE mexpr10 
HIGH mexpr10 
LOW mexpr10 
OFFSET mexpr10 
SEG mexpr10 
THIS mexpr10

mexpr11 ::= 
expr8 : expr8 ...

mexpr12 ::= 
mexpr13 [mexpr13 ...] ;Implied addition if bracket 
mexpr13 (mexpr13 ...);Implied addition if parenthesis 
mexpr13 '.' mexpr10
mexpr13 :=
LENGTH symbol
SIZE symbol
WIDTH symbol
MASK symbol
( mexpr1 )
[ mexpr ]
expr10

**Ideal mode expression grammar**

Expression parsing starts at `ideal_expr`.

```
ideal_expr ::= 
  pointer

itype ::= 
  UNKNOWN
  BYTE
  WORD
  DWORD
  PWORD
  FWORD
  QWORD
  TBYTE
  SHORT
  NEAR
  FAR
  PROC
  DATAPTR
  CODEPTR
  structure_name
  table_name
  enum_namer
  record_name
  TYPE pointer

pointer ::= 
  SMALL pointer ;If 386
  LARGE pointer ;If 386
  itype PTR pointer
  itype LOW pointer
  itype HIGH pointer
  itype pointer
  pointer2
```
pointer2 ::= 
pointer3 . symbol ... 
pointer3

pointer3 ::= 
expr : pointer3 
expr

eexpr ::= 
SYMTYPE expr 
eexpr2

eexpr2 ::= 
eexpr3 OR expr3 ... 
eexpr3 XOR expr3 ... 
eexpr3

eexpr3 ::= 
eexpr4 AND expr4 ... 
eexpr4

eexpr4 ::= 
NOT expr4 
eexpr5

eexpr5 ::= 
eexpr6 EQ expr6 ... 
eexpr6 NE expr6 ... 
eexpr6 LT expr6 ... 
eexpr6 LE expr6 ... 
eexpr6 GT expr6 ... 
eexpr6 GE expr6 ... 
eexpr6

eexpr6 ::= 
eexpr7 + expr7 ... 
eexpr7 - expr7 ... 
eexpr7

eexpr7 ::= 
eexpr8 * expr8 ... 
eexpr8 / expr8 ... 
eexpr8 MOD expr8 ... 
eexpr8 SHR expr8 ... 
eexpr8 SHL expr8 ... 
eexpr8

eexpr8 ::= 
+ expr8 
- expr8 
eexpr9
Keyword precedence

It's important to understand how Turbo Assembler parses source lines so that you can avoid writing code that produces unexpected results. For example, examine the following program fragment:

NAME SEGMENT

If you had written this line hoping to open a segment called NAME, you would be disappointed. Turbo Assembler recognizes the NAME directive before the SEGMENT directive, thus naming your code SEGMENT.

In general, Turbo Assembler determines the meaning of a line based on the first two symbols on the line. The left-most symbol is in the first position, while the symbol to its right is in the second position.

Ideal mode precedence

The following precedence rules for parsing lines apply to Ideal mode:

1 All keywords in the first position of the line have the highest priority (priority 1) and are checked first.
2 The keywords in the second position have priority 2 and are checked second.
**MASM mode precedence**

The precedence rules for parsing lines in MASM mode are much more complicated than in Ideal mode. There are three levels of priority instead of two, as follows:

1. The highest priority (priority 1) is assigned to certain keywords found in the first position, such as `NAME` or `%OUT`.

2. The next highest priority (priority 2) belongs to all symbols found in the second position.

3. All other keywords found in first position have the lowest priority (priority 3).

**Note**

Turbo Assembler treats priority 1 keywords like priority 3 keywords inside structure definitions. In this case, priority 2 keywords have the highest priority.

For example, in the code fragment

```
NAME SEGMENT
```

`NAME` is a priority 1 keyword, while `SEGMENT` is a priority 2 keyword. Therefore, Turbo Assembler will interpret this line as a `NAME` directive rather than a `SEGMENT` directive. In another example,

```
MOV INSTR,1
```

`MOV` is a priority 3 keyword, while `INSTR` is a priority 2 keyword. Thus, Turbo Assembler interprets this line as an `INSTR` directive, not a `MOV` instruction (which you might have wanted).

**Keywords and predefined symbols**

This section contains a complete listing of all Turbo Assembler keywords.

The values in parentheses next to keywords indicate the priority of the keyword (1 or 2) in MASM mode. Keywords are labeled with a priority only if they have priority 1 or 2. All others are assumed to be priority 3. Turbo Assembler recognizes the keyword only if it finds them. In MASM mode, priority 1 or 3 keywords always are located in the first position, while priority 2 keywords occur in the second position.

An M next to a keyword indicates that you can use a keyword only in MASM mode, and an I indicates a keyword that is available only in Ideal mode. If there is no letter, the keyword works in either mode. A number next to the keyword indicates its priority.

**Directive keywords**

The following list contains all Turbo Assembler directive keywords. The keywords are grouped by the version of Turbo Assembler in which they were introduced.
These keywords were introduced in Turbo Assembler 1.0.

Turbo Assembler 5.0 (TASM32) supports most of the features of Microsoft MASM version 6.1. This Appendix documents the new features added to Turbo Assembler specifically to provide compatibility with MASM 6.0/6.1.

Basic data types

Turbo Assembler now supports the use of type names as directives when defining variables. For example, the line:

```
var DB 10
```

can now be written as:

```
var BYTE 10
```

Table C.1 shows the type names and their equivalent directives.

<table>
<thead>
<tr>
<th>Type</th>
<th>Equivalent directive</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>DB</td>
</tr>
<tr>
<td>DWORD</td>
<td>DD</td>
</tr>
<tr>

<td>DF</td>
</tr>
<tr>
<td>QWORD</td>
<td>DQ</td>
</tr>
<tr>
<td>TBYTE</td>
<td>DT</td>
</tr>
<tr>
<td>WORD</td>
<td>DW</td>
</tr>
</tbody>
</table>
Signed types
Table C.2 lists the specifications of the new signed integer types.

Table C.2  Signed integer data types

<table>
<thead>
<tr>
<th>Type</th>
<th>Bytes</th>
<th>Value range</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBYTE</td>
<td>1</td>
<td>-128 to +127</td>

</tr>
<tr>
<td>SDWORD</td>
<td>4</td>
<td>-2,147,483,648 to +2,147,483,647</td>
</tr>
</tbody>
</table>

Floating-point types
Table C.3 lists the specifications for the new floating point types.

Table C.3  Floating-point data types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Bits</th>
<th>Significant digits</th>
<th>Approximate range</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL4</td>
<td>Short real</td>
<td>32</td>
<td>6-7</td>
<td>1.18 × 10⁻³⁸ to 3.40 × 10³⁸</td>
</tr>
<tr>
<td>REAL8</td>
<td>Long real</td>
<td>64</td>
<td>15-16</td>
<td>2.23 × 10⁻³⁰⁸ to 1.79 × 10³⁰⁸</td>
</tr>
<tr>
<td>REAL10</td>
<td>10-byte real</td>
<td>80</td>
<td>19</td>
<td>3.37 × 10⁻⁴⁹³² to 1.18 × 10⁴⁹³²</td>
</tr>
</tbody>
</table>

Floating point constants can be designated as decimal constants or encoded hexadecimal constants, as shown in the following examples:

; Real decimal numbers
dshort REAL4 34.56 ;IEEE format
ddouble REAL8 3.456E1 ;IEEE format
dtenbyte REAL10 3456.0E-2 ;10-byte real format

; Hexadecimals, note the required trailing "r" and leading decimal digit
hexshort REAL4 4E7000000r ;IEEE short
hexdouble REAL8 4E70000000000000r ;IEEE long
hextenbyte REAL10 4E776000000000000000r;10-byte real

New decision and looping directives

Turbo Assembler now supports several high level directives to permit program structures similar to those in higher level languages, such as C++ and Object Pascal. These directives generate code for loops and decisions, which are executed depending on the status of a conditional statement. The conditions are tested at run-time, and can use the new run-time operators ==, !=, >=, <=, >, <, &&, ||, and !.

.IF .ELSE .ELSEIF .ENDIF

The directives .IF, .ELSE, .ELSEIF, .ENDIF generate conditional jumps. If the expression following .IF evaluates to true, then the statements following the .IF are executed until an .ELSE (if any), .ELSEIF (if any), or .ENDIF directive is encountered. If the .IF expression evaluates to false, the statements following the .ELSE (if any) are executed until an .ENDIF directive is encountered. Use .ELSEIF to cause a secondary expression to be evaluated if the .IF expression evaluates to false.
The syntax for the .IF directives is:

`.IF expression1
statements
[.ELSEIF expression2
statements]
[.ELSE
statements]
.ENDIF`

Example

`.IF bx == 16 ; if the value in bx equals 16
mov ax,20
ELSE ; if the value in bx does not equal 16
mov ax,30
ENDIF

.WHILE .ENDW

The .WHILE directive executes the statements between the .WHILE and the .ENDW as long as the expression following .WHILE evaluates to true, or until a .BREAK directive is encountered. Because the expression is evaluated at the beginning of the loop, the statements within the loop will not execute at all if the expression initially evaluates to false. If a .CONTINUE directive is encountered within the body of the loop, control is passed immediately back to the .WHILE where the expression is re-evaluated. If .BREAK is encountered, control is immediately passed to the statement following the .ENDW directive.

The syntax for the .WHILE directives is:

`.WHILE expression
statements
.ENDW`

Example

`mov ax, 0 ; initialize ax to 0
.WHILE ax < 128 ; while ax is less than 128
mov dx, cx ; put the value of cx in dx
.IF dx == bx ; if dx and bx are equal
mov ax, dx ; put the value of dx in ax
.CONTINUE ; re-evaluate .WHILE expression
.ELSEIF ax == dx ; if ax equals dx
.BREAK ; break out of the .WHILE loop
.ENDIF
inc ax ; increment ax by 1
.ENDW ; end of .WHILE loop`
The .REPEAT directive executes the statements between the .REPEAT and the .UNTIL as long as the expression following the .UNTIL (or .UNTILCXZ) evaluates to true, or until a .BREAK directive is encountered. Because the expression is evaluated at the end of the loop, the statements within the loop will execute at least once, even if the expression initially evaluates to false. If a .CONTINUE directive is encountered within the body of the loop, control is passed immediately to the .UNTIL where the expression is re-evaluated. If .BREAK is encountered, control is immediately passed to the statement following the .UNTIL (or .UNTILCXZ) directive. The .UNTIL directive generates conditional jumps. The .UNTILCXZ directive generates a LOOP instruction.

The syntax for the .REPEAT directives is:

```
.REPEAT
  statements
.UNTIL expression
```

Example

```
mov ax, 0              ; initialize ax to 0
.REPEAT                ; while ax is less than 128
  inc ax               ; increment ax by 1
.UNTIL ax >= 128       ; end of .REPEAT loop
```

.BREAK .CONTINUE

As noted above, .BREAK and .CONTINUE can be used to alter the program flow within a loop. .CONTINUE causes the loop to immediately re-evaluate its expression, bypassing any remaining statements in the loop. .BREAK terminates the loop and passes control to the statement following the end of the loop.

Both .BREAK and .CONTINUE can be combined with an optional .IF directive. If the .IF expression evaluates to true, the .BREAK or .CONTINUE are carried out, otherwise they are ignored.

Example

```
mov ax, bx
.WHILE ax != cx
  .BREAK .IF ax == dx
  .CONTINUE .IF ax > dx
  inc ax
.ENDW
```
Logical operators

Turbo Assembler now supports several C-like logical operators, as shown in Table C.4.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>is equal to</td>
</tr>
<tr>
<td>!=</td>
<td>is not equal to</td>
</tr>
<tr>
<td>&gt;=</td>
<td>is greater than or equal to</td>
</tr>
<tr>
<td>&lt;=</td>
<td>is less than or equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>is greater than</td>
</tr>
<tr>
<td>&lt;</td>
<td>is less than</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>and</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>!</td>
<td>not</td>
</tr>
<tr>
<td>&amp;</td>
<td>bit test</td>
</tr>
</tbody>
</table>

Using flags in conditions

Turbo Assembler permits the use flag value in conditions. The supported flag names are \texttt{ZERO?}, \texttt{CARRY?}, \texttt{OVERFLOW?}, \texttt{SIGN?}, and \texttt{PARITY?}. For example, to use the value of the CARRY flag in a loop expression, use:

```
.WHILE (CARRY?) ; if the CARRY flag is set...
  statements
.ENDW
```

Text Macros

A string of characters can be given a symbolic name, and have that name used in the source code rather than the string itself. The named text is referred to as a 	extit{text macro}. Use the \texttt{TEXTEQU} directive to define a text macro.

To assign a literal string to a text macro, enclose the string in angle brackets (<>). For example:

```
myString \texttt{TEXTEQU} <This is my string>
```

To assign one macro to another text macro, assign the macro name as in the example below:

```
myString \texttt{TEXTEQU} <This is my string>
myNewString \texttt{TEXTEQU} myString ;value of myString now in myNewString as well
```

To assign a text representation of a constant expression to a text macro, precede the expression with a percent sign (%). For example:

```
value \texttt{TEXTEQU} $(1 + num)$; assigns text representation of resolved expression to value
```
Text macros are useful for naming strings of text that do not evaluate to integers. For example:

```
pi    TEXTEQU <3.14159> ; floating point constant
WPT   TEXTEQU <WORD PTR> ; keywords
arg   TEXTEQU <[bp+4]>   ; expression
```

**Macro repeat blocks with loop directives**

Turbo Assembler supports "repeat blocks", or unnamed macros within a loop directive. The loop directive generates the statements inside the repeat block a specified number of times.

**REPEAT loops**

Use REPEAT to specify the number of times to generate the statements inside the macro. The syntax is:

```
REPEAT constant
statements
ENDM
```

**Example**

```
number LABEL BYTE   ; name the generated data
counter = 0         ; initialize counter
REPEAT 128
    BYTE counter ; allocate a new number
    counter = counter + 1; increment counter
ENDM
```

**FOR loops**

Use the FOR loop to iterate through a list of arguments, using the first argument the first time through, the second argument the second time through, and so on. The syntax is:

```
FOR parameter, <argumentList>
statements
ENDM
```

The parameter represents the name of each argument inside the FOR block. The argumentList is comma separated and enclosed in angle brackets.

**Example**

```
powers LABEL BYTE
FOR arg, <1,2,4,8,16,32,64,128>
    BYTE arg DUP (arg)
ENDM
```
The first iteration through the **FOR** loop sets **arg** to 1. The second iteration sets **arg** to 2. The third sets **arg** to 4, and so on.

Text macros may be used in place of literal strings of values. The **VARARG** directive can be used in the *argumentList* to create a variable number of arguments.

**FORC loops**

**FORC** loops are almost identical to **FOR** loops, except that the *argumentList* is given a a string, rather than as a comma separated list. The loop reads the string, character by character (including spaces), and uses one character per iteration. The syntax is:

```
FORC parameter, <text>
    statements
ENDM
```

The *parameter* represents the name of each argument inside the **FOR** block. The *text* is a character string and enclosed in angle brackets.

**Example**

```
alphabet LABEL BYTE
FORC arg, <ABCDEFGHIJKLMNOPQRSTUVWXYZ>
    BYTE 'arg'       ; allocate letter
ENDM
```

**New Directives**

For MASM compatibility, Turbo Assembler now supports the directive **STRUCT**, **EXTERN**, and **PROTO**. These directives are synonyms for the **STRUC**, **EXTRN**, and **PROCDESC** directives, respectively.

**ECHO directive**

The **ECHO** directive displays its argument to the standard output device during assembly. It is useful for debugging purposes. The syntax is:

```
ECHO argument
```

**EXTERNDEF directive**

Turbo Assembler treats **EXTERNDEF** as a **PUBLIC** declaration in the defining module, and as an external declaration in the referencing module(s). Use **EXTERNDEF** to make a variable or procedure common to two or more modules. If an **EXTERNDEF** variable or procedure is defined but not referenced in a given module, the **EXTERNDEF** is ignored; you need not create a symbol as you would using **EXTERN**. The syntax of the **EXTERNDEF** statement is:

```
EXTERNDEF [langType] name : type
```
OPTION directive

The OPTION directive lets you make global changes to the behavior of the assembler. The basic syntax of the directive is:

OPTION argument

For example, to make the expression word size 16 bits, use the statement:

    OPTION EXPR16

To make the expression word size 32 bits, use the statement:

    OPTION EXPR32

The available options are listed below:

CASEMAP: NONE/NOTPUBLIC/ALL

NONE causes internal symbol recognition to be case sensitive, and causes the case of identifiers in the .OBJ file to be the same as specified in the EXTERNDEF, PUBLIC, or COMM statement.

NOTPUBLIC (default) causes case insensitivity for internal symbol recognition, and has the same behavior as NONE for identifiers in .OBJ files.

ALL specifies universal case insensitivity and converts all identifiers to uppercase.

DOTNAME/NODOTNAME

Enables or disables the use of the dot (.) as the leading character in variable, macro, structure, union, and member names. The default is disabled.

EMULATOR/NOEMULATOR

NOEMULATOR (default) tells the assembler to generate floating point math coprocessor instructions directly.

EMULATOR generates floating point math instructions with special fixups for linking with a coprocessor emulator library.

EXPR16/EXPR32

Sets the expression word size to 16 or 32 bits. The default is 32 bits.

LJMP/NOLJMP

Enables or disables automatic conditional-jump lengthening. The default is enabled.

NOKEYWORD: <keywordList>

Disables the keywords listed in keywordList. For example:

    OPTION NOKEYWORD:<MASK EXPORT NAME>
PROC: PRIVATE/PUBLIC/EXPORT
Allows you to set the default PROC visibility as PRIVATE, PUBLIC, or EXPORT. The default is PUBLIC.

SCOPED/NOSCOPED
SCOPED (the default) guarantees that all labels inside procedures are local to the procedure.

SEGMENT: USE16/USE32/FLAT
Sets the global default segment size and the default address size for external symbols defined outside any segment.

Visibility in procedure declarations
Turbo Assembler supports three visibility modes in procedure (PROC) declarations; PRIVATE, PUBLIC, and EXPORT. The visibility indicates whether the procedure is available to other modules. PUBLIC procedures are available to other modules. All procedures are PUBLIC by default. PRIVATE procedures are available only within the module in which they are declared. Code in other modules cannot call PRIVATE procedures. If the visibility is EXPORT, the linker places the procedure’s name in the export table for segmented executables. EXPORT also enables PUBLIC visibility.

Distance in procedure declarations
In addition to the ability to specify NEAR or FAR distance in procedure (PROC) declarations, Turbo Assembler now supports the modifiers NEAR16, NEAR32, FAR16, and FAR32 when programming for the 80386, and up, and using both 16 and 32-bit segments.

SIZE operator in MASM mode
In MASM mode the size operator returns the values in table C.5 for the given labels.

<table>
<thead>
<tr>
<th>Label</th>
<th>SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHORT</td>
<td>0FF01h</td>
</tr>
<tr>
<td>NEAR16</td>
<td>0FF02h</td>
</tr>
<tr>
<td>NEAR32</td>
<td>0FF04h</td>
</tr>
<tr>
<td>FAR16</td>
<td>0FF05h</td>
</tr>
<tr>
<td>FAR32</td>
<td>0FF06h</td>
</tr>
</tbody>
</table>
Compatibility issues

Turbo Assembler in MASM mode is very compatible with MASM version 6.1. However, 100% compatibility is an ideal that can only be approached, since there is no formal specification for the language and different versions of MASM are not even compatible with each other.

For most programs, you will have no problem using Turbo Assembler as a direct replacement for MASM. Occasionally, Turbo Assembler will issue warnings or errors where MASM would not, which usually means that MASM has not detected an erroneous statement. For example, MASM accepts

```
abc EQU [BP+2]
PUBLIC abc
```

and generates a nonsense object file. Turbo Assembler correctly detects this and many other questionable constructs.

If you are having trouble assembling a program with Turbo Assembler, you might try using the **QUIRKS** directive (which enables potentially troublesome features of MASM). For example,

```
TASM /JQUIRKS MYFILE
```

might make your program assemble properly. If it does, add **QUIRKS** to the top of your source file. Even better, review Chapter 3 and determine which statement in your source file needs the **QUIRKS** directive. Then you can rewrite the line(s) of code so that you don't even have to use **QUIRKS**.

For maximum compatibility with MASM, you should use the **NOSMART** directive along with **QUIRKS** mode.

One-pass versus two-pass assembly

Normally, Turbo Assembler performs only one pass when assembling code, while MASM performs two. This feature gives Turbo Assembler a speed advantage, but can introduce minor incompatibilities when forward references and pass-dependent constructions are involved. The command-line option /m specifies the number of passes desired. For maximum compatibility with MASM, two passes (/m2) should be used. (See Chapter 2 for a complete discussion of this option.) The /m2 command-line switch will generate a MASM-style compatibility when the following constructs are present:

- **IF1** and **IF2** directives
- **ERR1** and **ERR2** directives
- **ESLEIF1** and **ELSEIF2** directives
- Forward references with **IFDEF** or **IFNDEF**
- Forward references with the **.TYPE** operator
- Recursively defined numbers, such as **NMBR=NMBR+1**
• Forward-referenced or recursively defined text macros, such as
  LNAME CATSTR LNAME,<1>
• Forward-referenced macros

Environment variables

Turbo Assembler doesn’t use environment variables to control default options. However, you can place default options in a configuration file and then set up different configuration files for different projects.

If you use INCLUDE or MASM environment variables to configure MASM, you’ll have to make a configuration file for Turbo Assembler. Any options that you have specified using the MASM variable can simply be placed in the configuration file. Any directories that you have specified using the INCLUDE variable should be placed in the configuration file using the /I command-line option.

Microsoft binary floating-point format

By default, older versions of MASM generated floating-point numbers in a format incompatible with the IEEE standard floating-point format. MASM version 6.1 generates IEEE floating-point data by default and has the .MSFLOAT directive to specify that the older format be used.

Turbo Assembler does not support the old floating-point format, and therefore does not let you use .MSFLOAT.
This chapter describes all the messages that Turbo Assembler generates. Messages usually appear on the screen, but you can redirect them to a file or printer using the standard OS/2 redirection mechanism of putting the device or file name on the command line, preceded by the greater than (>) symbol. For example,

```
TASM MYFILE >ERRORS
```

Turbo Assembler generates several types of messages:

- Information messages
- Warning messages
- Error messages
- Fatal error messages

### Information messages

Turbo Assembler displays two information messages: one when it starts assembling your source file(s) and another when it has finished assembling each file. Here's a sample startup display:

```
Turbo Assembler Version 4.0 Copyright (C) 1988, 1993 Borland International
Assembling file: TEST.ASM
```

When Turbo Assembler finishes assembling your source file, it displays a message that summarizes the assembly process; the message looks like this:

```
Error messages: None
Warning messages: None
Passes: 1
Remaining memory: 279k
```

You can suppress all information messages by using the /T command-line option. This only suppresses the information messages if no errors occur during assembly. If there are any errors, the /T option has no effect and the normal startup and ending messages appear.
Warning and error messages

Warning messages let you know that something undesirable may have happened while assembling a source statement. This might be something such as the Turbo Assembler making an assumption that is usually valid, but might not always be correct. You should always examine the cause of warning messages to see if the generated code is what you wanted. Warning messages won't stop Turbo Assembler from generating an object file. These messages are displayed using the following format:

**Warning** filename(line) message

If the warning occurs while expanding a macro or repeat block, the warning message contains additional information, naming the macro and the line within it where the warning occurred:

**Warning** filename(line) macroname(macroline) message

Error messages, on the other hand, will prohibit Turbo Assembler from generating an object file, but assembly will continue to the end of the file. Here's a typical error message format:

**Error** filename(line) message

If the error occurs while expanding a macro or repeat block, the error message contains additional information, naming the macro and the line within it where the error occurred:

**Error** filename(line) macroname(macroline) message

Fatal error messages cause Turbo Assembler to immediately stop assembling your file. Whatever caused the error prohibited the assembler from being able to continue.

The following list arranges Turbo Assembler's messages in alphabetical order:

---

32-bit segments not allowed without .386
Has been extended to work with the new ability to specify USE32 in the .MODEL statement and the LARGESTACK command. Formerly was "USE32 not allowed without .386."

Argument mismatch
Argument sizes did not agree. For example,

```
foo proctype pascal :word, :dword
fooproc proc foo al:word, a2:dword
: endp

call fooproc,ax,bx ;Argument mismatch.
```

Argument needs type override
The expression needs to have a specific size or type supplied, since its size can't be determined from the context. For example,

```
mov [bx],l
```

You can usually correct this error by using the PTR operator to set the size of the operand:

```
mov WORD PTR[bx],l
```

Argument to operation or instruction has illegal size
An operation was attempted on something that could not support the required operation. For example,

```
Q LABEL QWORD
QNOT = not Q ;can't negate a qword
```
Arithmetic overflow
A loss of arithmetic precision occurred somewhere in the expression. For example,

X = 20000h * 20000h ; overflows 32 bits

All calculations are performed using 32-bit arithmetic.

ASSUME must be segment register
You have used something other than a segment register in an ASSUME statement. For example,

ASSUME ax:CODE

You can only use segment registers with the ASSUME directive.

Bad keyword in SEGMENT statement
One of the align/combine/use arguments to the SEGMENT directive is invalid. For example,

DATA SEGMENT PARA PUBLIC ; PARA should be PARA

Bad switch
You have used an invalid command-line option. See Chapter 2 for a description of the command-line options.

Can't add relative quantities
You have specified an expression that attempts to add together two addresses, which is a meaningless operation. For example,

ABC DB ?
DEF = ABC + ABC ; error, can't add two relatives

You can subtract two relative addresses, or you can add a constant to a relative address, as in:

XYZ DB 5 DUP (0)
XYZLEN EQU $
XYZLEN = SYZEND - XYZ ; perfectly legal
XYZ2 = XYZ + 2 ; legal also

Can't address with currently ASSUMEd segment registers
An expression contains a reference to a variable for which you have not specified the segment register needed to reach it. For example,

DSEG SEGMENT
ASSUME ds:DSEG
mov si,MPTR ; no segment register to reach XSEG
DSEG ENDS
XSEG SEGMENT
MPTR DW ?
XSEG ENDS

Can't convert to pointer
Part of the expression could not be converted to a memory pointer, for example, by using the PTR operator,

mov cl, [BYTE PTR al] ; can't make AL into pointer

Can't emulate 8087 instruction
The Turbo Assembler is set to generate emulated floating-point instructions, either via the /E command-line option or by using the EMUL directive, but the current instruction can't be emulated. For example,

EMUL
FNSAVE [WPTR] ; can't emulate this

The following instructions are not supported by floating-point emulators: FNSAVE, FNSTCW, FNSTENV, and FNSTSW.

Can't find @file
You have specified an indirect command file name that does not exist. Make sure that you supply the complete file name. Turbo Assembler does not presume any default extension for the file name. You've probably run out of space on the disk where you asked the cross-reference file to be written.
Can’t generate instance of type
You attempted to generate an instance of a named type that does not have an instance. For example,

```plaintext
can’t generate instance of type
Can’t locate file
You have specified a file name with the INCLUDE directive that can’t be found.

Can’t make variable public
The variable is already declared in such a way that it can’t be made public. For example,

```plaintext
can’t make variable public
Can’t override ES segment
The current statement specifies an override that can’t be used with that instruction. For example,

```plaintext
can’t override ES segment
Can’t subtract dissimilar relative quantities
An expression subtracts two addresses that can’t be subtracted from each other, such as when they are each in a different segment:

```plaintext
can’t subtract dissimilar relative quantities
Can’t use macro name in expression
A macro name was encountered as part of an expression. For example,

```plaintext
can’t use macro name in expression
Can’t use this outside macro
You have used a directive outside a macro definition that can only be used inside a macro definition. This includes directives like ENDM and EXITM. For example,

```plaintext
can’t use this outside macro
Code or data emission to undeclared segment
A statement that generated code or data is outside of any segment declared with the SEGMENT directive. For example,

```plaintext
code or data emission to undeclared segment
Constant assumed to mean immediate constant
This warning appears if you use an expression such as [0], which under MASM is interpreted as simply 0. For example,
Constant too large
You have entered a constant value that is properly formatted, but is too large. For example, you can only use numbers larger than \texttt{0fffh} when you have enabled 80386 or i486 instructions with the \texttt{.386/.386P} or \texttt{.486/.486P} directives.

CS not correctly assumed
A near CALL or JMP instruction can’t have as its target an address in a different segment. For example,

```assembly
SEG1 SEGMENT
LAB1 LABEL NEAR
SEG1 ENDS
SEG2 SEGMENT
    jmp LAB1 ; error, wrong segment
SEG2 ENDS
```

This error only occurs in MASM mode. Ideal mode correctly handles this situation.

CS override in protected mode
The current instruction requires a CS override, and you are assembling instructions for the 80286, 80386, or i486 in protected mode (\texttt{P286P}, \texttt{P386P}, or \texttt{P486} directives). For example,

```assembly
P286P
.CODE
CVAL DW ?
    mov CVAL,1 ; generates CS override
```

The \texttt{/P} command-line option enables this warning. When running in protected mode, instructions with CS overrides won’t work without you taking special measures.

CS unreachable from current segment
When defining a code label using colon (:), LABEL or PROC, the CS register is not assumed to either the current code segment or to a group that contains the current code segment. For example,

```assembly
PROG1 SEGMENT
    .ASSUME cs:PROG2
START: ; error, bad CS assume
```

This error only occurs in MASM mode. Ideal mode correctly handles this situation.

Data or code written to uninitialized segment
You have inadvertently written initialized code or data to an uninitialized segment. For example,

```assembly
.data?
msg db 'Hello',0 ; error, uninitialized segment
```

Declaration needs name
You have used a directive that needs a symbol name, but none has been supplied. For example,

```assembly
PROC ; error, PROC needs a name
    ret
ENDP
```

You must always supply a name as part of a SEGMENT, PROC, or STRUC declaration. In MASM mode, the name precedes the directive; in Ideal mode, the name comes after the directive.
Directive not allowed inside structure definition
You have used a directive inside a STRUC definition block that can't be used there. For example,

```assembly
X STRU
MEM1 DB ?
    ORG $+4 ;error, can't use ORG inside STRU
MEM2 DW ?
ENDS
```

Also, when declaring nested structures, you cannot give a name to any that are nested. For example,

```assembly
FOO STRU
    FOO2 STRUC ;can't name inside
ENDS
ENDS
```

If you want to use a named structure inside another structure, you must first define the structure and then use that structure name inside the second structure.

Duplicate dummy argument:
A macro defined with the MACRO directive has more than one dummy parameter with the same name. For example,

```assembly
XYZ MACRO A,A ;error, duplicate dummy name
    DB A
ENDM
```

Each dummy parameter in a macro definition must have a different name.

ELSE or ENDIF without IF
An ELSE or ENDIF directive has no matching IF directive to start a conditional assembly block. For example,

```assembly
BUF DB 10 DUP (?)
ENDIF ;error, no matching IFxxx
```

Error writing to listing file
You've probably run out of space on the disk where you asked the listing file to be written.

Error writing to object file
You've probably run out of space on the disk where you asked the object file to be written.

Expecting METHOD keyword
The extended structure statement for defining objects expects the keyword METHOD after the parent object.

Expecting offset quantity
An expression expected an operand that referred to an offset within a segment, but did not encounter the right sort of operand. For example,

```assembly
CODE SEGMENT
    mov ax,LOW CODE
CODE ENDS
```

Expecting offset or pointer quantity
An expression expected an operand that referred to an offset within a specific segment, but did not encounter the right sort of operand. For example,

```assembly
CODE SEGMENT
    mov ax,SEG CODE ;error, code is a segment not ;a location within a segment
CODE ENDS
```

Expecting pointer type
The current instruction expected an operand that referenced memory. For example,

```assembly
les di,4 ;no good, 4 is a constant
```
Expecting record field name
You used a SETFIELD or GETFIELD instruction without a field name following it.

Expecting register ID
The USES part of the CALL..METHOD expects register name(s).

Expecting scalar type
An instruction operand or operator expects a constant value. For example,

\[
\begin{align*}
BB & \text{ DB } 4 \\
\text{rol ax, BB} &; \text{ROL needs constant}
\end{align*}
\]

Expecting segment or group quantity
A statement required a segment or group name, but did not find one. For example,

\[
\begin{align*}
\text{DATA SEGMENT} \\
\text{ASSUME ds:FOO} &; \text{error, FOO is not group or segment} \\
\text{name} \\
\text{FOO DW } 0 \\
\text{DATA ENDS}
\end{align*}
\]

Extra characters on line
A valid expression was encountered, but there are still characters left on the line. For example,

\[
\begin{align*}
\text{ABC = 4 shl } 3 &; \text{missing operator between 3 and 3}
\end{align*}
\]

This error often happens in conjunction with another error that caused the expression parser to lose track of what you intended to do.

File not found
The source file name you specified on the command line does not exist. Make sure you typed the name correctly, and that you included any necessary drive or path information if the file is not in the current directory.

File was changed or deleted while assembly in progress
Another program, such as a pop-up utility, has changed or deleted the file after Turbo Assembler opened it. Turbo Assembler can't reopen a file that was previously opened successfully.

Forward reference needs override
An expression containing a forward-referenced variable resulted in more code being required than Turbo Assembler anticipated. This can happen either when the variable is unexpectedly a far address for a JMP or CALL or when the variable requires a segment override in order to access it. For example,

\[
\begin{align*}
\text{ASSUME cs:DATA} \\
\text{call A} &; \text{presume near call} \\
\text{A PROC FAR} &; \text{oops, it's far} \\
\text{mov ax, MEMVAR} &; \text{doesn't know it needs override} \\
\text{DATA SEGMENT} \\
\text{MEMVAR DW ?} &; \text{oops, needs override}
\end{align*}
\]

Correct this by explicitly supplying the segment override or FAR override.

Global type doesn't match symbol type
This warning is given when a symbol is declared using the GLOBAL statement and is also defined in the same module, but the type specified in the GLOBAL and the actual type of the symbol don't agree.
**ID not member of structure**

In Ideal mode, you have specified a symbol that is not a structure member name after the period (.) structure member operator. For example,

```
IDEAL
STRUC DEMO
  DB ?
ENDS
COUNT DW 0
  mov ax,[(DEMO bx).COUNT] ;COUNT not part of structure
```

You must follow the period with the name of a member that belongs to the structure name that precedes the period. This error often happens in conjunction with another error that caused the expression parser to lose track of what you intended to do.

**Illegal forward reference**

A symbol has been referred to that has not yet been defined, and a directive or operator requires that its argument not be forward-referenced. For example,

```
IF MYSYM ;error, MYSYM not defined yet
  ;
ENDIF
MYSYM EQU 1
```

Forward references may not be used in the argument to any of the IFxxx directives, nor as the count in a DUP expression.

**Illegal immediate**

An instruction has an immediate (constant) operand where one is not allowed. For example,

```
mov 4,al
```

**Illegal indexing mode**

An instruction has an operand that specifies an illegal combination of registers. For example,

```
mov al,[si+ax]
```

On all processors except the 80386, the only valid combinations of index registers are: BX, BP, SI, DI, BX+SI, BX+DI, BP+SI, BP+DI.

**Illegal instruction**

A source line starts with a symbol that is neither one of the known directives nor a valid instruction mnemonic.

```
move ax,4 ;should be "MOV"
```

**Illegal instruction for currently selected processor(s)**

A source line specifies an instruction that can't be assembled for the current processor. For example,

```
.8086
push 1234h ;no immediate push on 8086
```

When Turbo Assembler first starts assembling a source file, it generates instructions for the 8086 processor, unless told to do otherwise.

If you wish to use the extended instruction mnemonics available on the 186/286/386 processors, you must use one of the directives that enables those instructions (P186, P286, P386).

**Illegal local argument**

The LOCAL directive inside a macro definition has an argument that is not a valid symbol name. For example,

```
X MACRO
LOCAL 123 ;not a symbol
ENDM
```
Illegal local symbol prefix
The argument to the LOCALS directive specifies an invalid start for local symbols. For example,

```
LOCALS XYZ ;error, not 2 characters
```

The local symbol prefix must be exactly two characters that themselves are a valid symbol name, such as _- @@, and so on (the default is @@).

Illegal macro argument
A macro defined with the MACRO directive has a dummy argument that is not a valid symbol name. For example,

```
X MACRO 123 ;invalid dummy argument
ENDM
```

Illegal memory reference
An instruction has an operand that refers to a memory location, but a memory location is not allowed for that operand. For example,

```
mov [bx],BYTE PTR A ;error, can't move from MEM to MEM
```

Here, both operands refer to a memory location, which is not a legal form of the MOV instruction. On the 80x86 family of processors, only one of the operands to an instruction can refer to a memory location.

Illegal number
A number contains one or more characters that are not valid for that type of number. For example,

```
Z = OABCGh
```

Here, G is not a valid letter in a hexadecimal number.

Illegal origin address
You have entered an invalid address to set the current segment location ($). You can enter either a constant or an expression using the location counter ($), or a symbol in the current segment.

Illegal override in structure
You have attempted to initialize a structure member that was defined using the DUP operator. You can only initialize structure members that were declared without DUP.

Illegal override register
A register other than a segment register (CS, DS, ES, SS, and on the 80386, FS and GS) was used as a segment override, preceding the colon (:) operator. For example,

```
mov dx:XYZ,1 ;DX not a segment register
```

Illegal radix
The number supplied to the .RADIX directive that sets the default number radix is invalid. For example,

```
.RADIX 7 ;no good
```

The radix can only be set to one of 2, 8, 10, or 16. The number is interpreted as decimal no matter what the current default radix is.

Illegal register for instruction
An illegal register was used as the source of a SETFIELD instruction or the destination of a GETFIELD instruction.

Illegal register multiplier
You have attempted to multiply a register by a value, which is not a legal operation; for example,

```
mov ax*3,1
```

The only context where you can multiply a register by a constant expression is when specifying a scaled index operand on the 80386 processor.

Illegal segment address
This error appears if an address greater than 65,535 is specified as a constant segment address; for example,

```
FOO SEGMENT AT 12345h
```

Illegal use of constant
A constant appears as part of an expression where constants can’t be used. For example,

```
mov bx+4,5
```
Illegal use of register
A register name appeared in an expression where it can't be used. For example,
\[ X = 4 \text{ shl} \ ax \quad ;\text{can't use register with SHL operator} \]

Illegal use of segment register
A segment register name appears as part of an instruction or expression where segment registers cannot be used.
For example,
\[ \text{add `SS,4} \quad ;\text{ADD can't use segment regs} \]

Illegal USES register
You have entered an invalid register to push and pop as part of entering and leaving a procedure. The valid registers follow:
AX \quad BX \quad CX \quad DI \nDS \quad DX \quad ES \quad SI \n
If you have enabled the 80386 processor with the .386 or .386P directive, you can use the 32-bit equivalents for these registers.

Illegal version ID
Occurs when an illegal version ID was selected in the VERSION statement or /U switch.

Illegal warning ID
You have entered an invalid three-character warning identifier. See the options discussed in Chapter 2 for a complete list of the allowed warning identifiers.

Instruction can be compacted with override
The code generated contains NOP padding, due to some forward-referenced symbol. You can either remove the forward reference or explicitly provide the type information as part of the expression. For example,
\[ \text{jmp X} \quad ;\text{warning here} \n\text{jmp SHORT X} \quad ;\text{no warning} \]

Insufficient memory to process command line
You have specified a command line that is either longer than 64K or can’t be expanded in the available memory.
Either simplify the command line or run Turbo Assembler with more memory free.

Internal error
This message should never happen during normal operation of Turbo Assembler. Save the file(s) that caused the error and report it to Borland’s Technical Support department.

Invalid command line
The command line that you used to start Turbo Assembler is badly formed. For example,
\[ \text{TASM ,MYFILE} \]
does not specify a source file to assemble. See Chapter 2 for a complete description of the Turbo Assembler command line.

Invalid model type
The model directive has an invalid memory model keyword. For example,
\[ .\text{MODEL GIGANTIC} \]
Valid memory models are tiny, small, compact, medium, large, and huge.

Invalid number after
You have specified a valid command-line switch (option), but have not supplied a valid numeric argument following the switch. See Chapter 2 for a discussion of the command-line options.

Invalid operand(s) to instruction
The instruction has a combination of operands that are not permitted. For example,
\[ \text{fadd ST(2),ST(3)} \]
Here, \text{FADD} can only refer to one stack register by name; the other must be the stack top.
Labels can't start with numeric characters
You have entered a symbol that is neither a valid number nor a valid symbol name, such as 123XYZ.

Language differs from procedure type
You attempted to use a different language than what was contained in the procedure type declaration. For example,

```
foo proctype windows pascal :word
fooproc proc foo al:word
:
endp
call fooproc c,ax ;Language doesn't match.
```

Language doesn't support variable-length arguments
You specified a variable-length stack frame with a language that doesn't support it. For example,

```
foo proctype pascal :word, :unknown ;Pascal can't have ;variable arguments.
```

Line too long—truncating
The current line in the source file is longer than 255 characters. The excess characters will be ignored.

Location counter overflow
The current segment has filled up, and subsequent code or data will overwrite the beginning of the segment. For example,

```
ORG OFFFOh
ARRAY DW 20 DUP (0) ;overflow
```

Method CALL requires object name
The CALL..METHOD statement cannot obtain the object type from this instance pointer. You must specify the object name.

Missing argument list
An IRP or IRPC repeat block directive does not have an argument to substitute for the dummy parameter. For example,

```
IRP X ;no argument list
    DB X
ENDM
```

IRP and IRPC must always have both a dummy parameter and an argument list.

Missing argument or <
You forgot the angle brackets or the entire expression in an expression that requires them. For example,

```
ifb ;needs an argument in <>s
```

Missing argument size variable
An ARG or LOCAL directive does not have a symbol name following the optional = at the end of the statement. For example,

```
ARG A:WORD,B:DWORD= ;error, no name after =
LOCAL X:TBYTE= ;same error here
```

ARG and LOCAL must always have a symbol name if you have used the optional equal sign (=) to indicate that you want to define a size variable.

Missing COMM ID
A COMM directive does not have a symbol name before the type specifier. For example,

```
COMM NEAR ;error, no symbol name before "NEAR"
```

COMM must always have a symbol name before the type specifier, followed by a colon (:) and then the type specifier.
**Missing dummy argument**
An IRP or IRPC repeat block directive does not have a dummy parameter. For example,

```
RP
    DB X  ;no dummy parameter
ENDM
```

IRP and IRPC must always have both a dummy parameter and an argument list.

**Missing end quote**
A string or character constant did not end with a quote character. For example,

```
DB "abc"
mov al,'X
```

You should always end a character or string constant with a quote character matching the one that started it.

**Missing macro ID**
A macro defined with the MACRO directive has not been given a name. For example,

```
MACRO
    DB A
ENDM
```

Macros must always be given a name when they are defined.

**Missing module name**
You have used the NAME directive but you haven’t supplied a module name after the directive. Remember that the NAME directive only has an effect in Ideal mode.

**Missing or illegal language ID**
You have entered something other than one of the allowed language identifiers after the .MODEL directive. See Chapter 7 for a complete description of the .MODEL directive.

**Missing or illegal type specifier**
A statement that needed a type specifier (like BYTE, WORD, and so on) did not find one where expected. For example,

```
RED LABEL XXX  ;error, "XXX" is not a type specifier
```

**Missing table member ID**
A CALL..METHOD statement was missing the method name after the METHOD keyword.

**Missing term in list**
In Ideal mode, a directive that can accept multiple arguments (EXTRN, PUBLIC, and so on) separated by commas does not have an argument after one of the commas in the list. For example,

```
EXTRN XXX:BYTE,,YYY:WORD
```

In Ideal mode, all argument lists must have their elements separated by precisely one comma, with no comma at the end of the list.

**Missing text macro**
You have not supplied a text macro argument to a directive that requires one. For example,

```
NEWSTR SUBSTR  ;ERROR - SUBSTR NEEDS ARGUMENTS
```

**Model must be specified first**
You used one of the simplified segmentation directives without first specifying a memory model. For example,

```
.CODE  ;error, no .MODEL first
```

You must always specify a memory model using the .MODEL directive before using any of the other simplified segmentation directives.
Module is pass-dependent—compatibility pass was done
This warning occurs if a pass-dependent construction was encountered and the /m command-line switch was specified. A MASM-compatible pass was done.
You put a symbol name after a directive, and the symbol name should come first. For example,

```
STRUC ABC ;error, ABC must come before STRUC
```

Since Ideal mode expects the name to come after the directive, you will encounter this error if you try to assemble Ideal mode programs in MASM mode.

Near jump or call to different CS
This error occurs if the user attempts to perform a NEAR CALL or JMP to a symbol that's defined in an area where CS is assumed to a different segment.

Need address or register
An instruction does not have a second operand supplied, even though there is a comma present to separate two operands; for example,

```
mov ax, ;no second operand
```

Need angle brackets for structure fill
A statement that allocates storage for a structure does not specify an initializer list. For example,

```
STR1 STRU
M1 DW ?
M2 DD ?
ENDS
STR1 ;no initializer list
```

Need colon
An EXTRN, GLOBAL, ARG, or LOCAL statement is missing the colon after the type specifier (BYTE, WORD, and so on). For example,

```
EXTRN X BYTE,Y:WORD ;X has no colon
```

Need expression
An expression has an operator that is missing an operand. For example,

```
X = 4 + * .6
```

Need file name after INCLUDE
An INCLUDE directive did not have a file name after it. For example,

```
INCLUDE ;include what?
```

In Ideal mode, the file name must be enclosed in quotes.

Need left parenthesis
A left parenthesis was omitted that is required in the expression syntax. For example,

```
DB 4 DUP 7
```

You must always enclose the expression after the DUP operator in parentheses.

Need method name
The CALL.METHOD statement requires a method name after the METHOD keyword.

Need pointer expression
This error only occurs in Ideal mode and indicates that the expression between brackets ([ ]) does not evaluate to a memory pointer. For example,

```
mov ax,[WORD PTR]
```

In Ideal mode, you must always supply a memory-referencing expression between the brackets.
**Need quoted string**
You have entered something other than a string of characters between quotes where it is required. In Ideal mode, several directives require their argument to be a quoted string. For example,

```
IDEAL
    DISPLAY "ALL DONE"
```

**Need register in expression**
You have entered an expression that does not contain a register name where one is required.

**Need right angle bracket**
An expression that initializes a structure, union, or record does not end with a > to match the < that started the initializer list. For example,

```
MYSTRUC STRUCNAME <1,2,3
```

**Need right curly bracket**
Occurs during a named structure, table, or record fill when a ‘}’ is expected but not found.

**Need right parenthesis**
An expression contains a left parenthesis, but no matching right parenthesis. For example,

```
X = 5 * (4 + 3
```
You must always use left and right parentheses in matching pairs.

**Need right curly bracket**
An expression that references a memory location does not end with a ] to match the [ that started the expression. For example,

```
mov ax,[si ] ;error, no closing ] after SI
```
You must always use square brackets in matching pairs.

**Need stack argument**
A floating-point instruction does not have a second operand supplied, even though there is a comma present to separate two operands. For example,

```
fadd ST,
```

**Need structure member name**
In Ideal mode, the period (.) structure member operator was followed by something that was not a structure member name. For example,

```
IDEAL
    STRUC DEMO
        DB ?
    ENDS
    COUNT DW 0
    mov ax,[(DEMO bx).]
```
You must always follow the period operator with the name of a member in the structure to its left.

**Not expecting group or segment quantity**
You have used a group or segment name where it can’t be used. For example,

```
CODE SEGMENT
    rol ax,CODE ;error, can't use segment name here
```

**One non-null field allowed per union expansion**
When initializing a union defined with the UNION directive, more than one value was supplied. For example,

```
U UNION
    DW ?
    DD ?
ENDS
UINST U <1,2> ;error, should be <?,2> or <1,?>
```
A union can only be initialized to one value.
Only one startup sequence allowed
This error appears if you have more than one .STARTUP or STARTUPCODE statement in a module.

Open conditional
The end of the source file has been reached as defined with the END directive, but a conditional assembly block started with one of the IFxxx directives has not been ended with the ENDIF directive. For example,

```
IF BIGBUF
END ;no ENDIF before END
```

This usually happens when you type END instead of ENDIF to end a conditional block.

Open procedure
The end of the source file has been reached as defined with the END directive, but a procedure block started with the PROC directive has not been ended with the ENDP directive. For example,

```
MYFUNC PROC
END ;no ENDIF before ENDP
```

This usually happens when you type END instead of ENDP to end a procedure block.

Open segment
The end of the source file has been reached as defined with the END directive, but a segment started with the SEGMENT directive has not been ended with the ENDS directive. For example,

```
DATA SEGMENT
END ;no ENDS before END
```

This usually happens when you type END instead of ENDS to end a segment.

Open structure definition
The end of the source file has been reached as defined with the END directive, but a structure started with the STRUC directive has not been ended with the ENDS directive. For example,

```
X STRUC
VAL1 DW ?
END ;no ENDS before it
```

This usually happens when you type END instead of ENDS to end a structure definition.

Operand types do not match
The size of an instruction operand does not match either the other operand or one valid for the instruction; for example,

```
ABC DB 5
```

```
: mov ax,ABC
```

Operation illegal with procedure type
You used the structure member operator on an expression whose type is a procedure. For example,

```
foo proctype pascal :word
```

```
: mov ax,[foo ptr [bx]].member ;Things of type FO0
     ;have no members
```

Operation illegal with static table member
A '.' operator was used to obtain the address of a static table member. This is illegal.

Out of hash space
The hash space has one entry for each symbol you define in your program. It starts out allowing 16,384 symbols to be defined, as long as Turbo Assembler is running with enough free memory. If your program has more than this many symbols, use the /KH command-line option to set the number of symbol entries you need in the hash table.
Out of memory
You don't have enough free memory for Turbo Assembler to assemble your file.
If you have any TSR (RAM-resident) programs installed, you can try removing them from memory and try
assembling your file again. You may have to reboot your system in order for memory to be properly freed.
Another solution is to split the source file into two or more source files, or rewrite portions of it so that it requires
less memory to assemble. You can also use shorter symbol names, reduce the number of comments in macros, and
reduce the number of forward references in your program.

Out of string space
You don't have enough free memory for symbol names, file names, forward-reference tracking information, and
macro text. A maximum of 512K is allowed, and your module has exceeded this maximum.

Pass-dependent construction encountered
The statement may not behave as you expect, due to the one-pass nature of Turbo Assembler. For example,
```assembly
IF1
    ;Happens on assembly pass
ENDIF
IF2
    ;Happens on listing pass
ENDIF
```
Most constructs that generate this error can be re-coded to avoid it, often by removing forward references.

Pointer expression needs brackets
In Ideal mode, the operand contained a memory-referencing symbol that was not surrounded by brackets to
indicate that it references a memory location. For example,
```assembly
B DB 0
mov al,B ;warning, Ideal mode needs [B]
```
Since MASM mode does not require the brackets, this is only a warning.

Positive count expected
A DUP expression has a repeat count less than zero. For example,
```assembly
BUF -1 DUP (?) ;error, count < 0
```
The count preceding a DUP must always be 1 or greater.

Procedure has too many arguments
A procedure was declared with too many arguments. For example,
```assembly
foo proc footype
    arg a1:word,a2:dword,a3:word
    nop ;too many arguments were declared for
    ;for this proc
endp
```

Procedure needs more arguments
A procedure was declared with too few arguments. For example,
```assembly
foo proc footype
    arg a1:word
    nop ;Needs a DWORD argument somewhere too.
    ret
endp
```

Record field too large
When you defined a record, the sum total of all the field widths exceeded 32 bits. For example,
```assembly
AREC RECORD RANGE:12,TOP:12,BOTTOM:12
```
Record member not found
A record member was specified in a named record fill that was not part of the specified record.

Recursive definition not allowed for EQU
An EQU definition contained the same name that you are defining within the definition itself. For example,

```
ABC EQU TWOTIMES ABC
```

Register must be AL or AX
An instruction which requires one operand to be the AL or AX register has been given an invalid operand. For example,

```
IN CL,dx ;error, 'IN' must be to AL or AX
```

Register must be DX
An instruction which requires one operand to be the DX register has been given an invalid operand. For example,

```
IN AL,cx ;error, must be DX register instead of CX
```

Relative jump out of range by _ bytes
A conditional jump tried to reference an address that was greater than 128 bytes before or 127 bytes after the current location. If this is in a USE32 segment, the conditional jump can reference between 32,768 bytes before and 32,767 bytes after the current location.

Relative quantity illegal
An instruction or directive has an operand that refers to a memory address in a way that can't be known at assembly time, and this is not allowed. For example,

```
DATA SEGMENT PUBLIC
X DB 0
IF OFFSET X GT 127 ;not known at assemble time
```

Reserved word used as symbol
You have created a symbol name in your program that Turbo Assembler reserves for its own use. Your program will assemble properly, but it is good practice not to use reserved words for your own symbol names.

Rotate count must be constant or CL
A shift or rotate instruction has been given an operand that is neither a constant nor the CL register. For example,

```
rol ax,DL ;error, can't use DL as count
```

You can only use a constant value or the CL register as the second operand to a rotate or shift instruction.

Rotate count out of range
A shift or rotate instruction has been given a second operand that is too large. For example,

```
 shl DL,3 ;error, 8086 can only shift by 1
.286
shr ax,40 ;error, max shift is 31
```

The 8086 processor only allows a shift count of 1, but the other processors allow a shift count up to 31.

Segment alignment not strict enough
The align boundary value supplied is invalid. Either it is not a power of 2, or it specifies an alignment stricter than that of the align type in the SEGMENT directive. For example,

```
DATA SEGMENT PARA
ALIGN 32 ;error, PARA is only 16
ALIGN 3 ;error, not power of 2
```

Appendix D, Error messages 277
Segment attributes illegally redefined
A SEGMENT directive reopen a segment that has been previously defined, and tries to give it different attributes. For example,

```
DATA SEGMENT BYTE PUBLI
DATA ENDS
DATA SEGMENT PARA ;error, previously had byte alignment
DATA ENDS
```

If you reopen a segment, the attributes you supply must either match exactly or be omitted entirely. If you don’t supply any attributes when reopening a segment, the old attributes will be used.

Segment name is superfluous
This warning appears with a .CODE xxx statement, where the model specified doesn’t allow more than code segment.

String too long
You have built a quoted string that is longer than the maximum allowed length of 255.

Style differs from procedure type
You attempted to use a different language style than the declaration of the procedure type contained. For example,

```
foo proctype windows pascal :word
fooproc proc foo a1:word
;
endp
```

call fooproc normal pascal,ax ;Style doesn't match.

Symbol already defined
The indicated symbol has previously been declared with the same type. For example,

```
BB DB 1,2,3
BB DB ? ;error, BB already defined
```

Symbol already different kind
The indicated symbol has already been declared before with a different type. For example,

```
BB DB 1,2,3
BB DW ? ;error, BB already a byte
```

Symbol has no width or mask
The operand of a WIDTH or MASK operator is not the name of a record or record field. For example,

```
B DB 0
```

```
mov ax,MASK B ;B is not a record field
```

Symbol is not a segment or already part of a group
The symbol has either already been placed in a group or it is not a segment name. For example,

```
DATA SEGMENT
DATA ENDS
DGROUP GROUP DATA
DGROUP2 GROUP DATA ;error, DATA already belongs to DGROUP
```

Text macro expansion exceeds maximum line length
This error occurs when expansion of a text macro causes the maximum allowable line length to be exceeded.
Too few arguments to procedure
You called a procedure using too few arguments. For example,

```
foo proctype pascal :word, :dword
fooproc proc foo a1:word, a2:dword

endp
```
call fooproc,ax ;Too few arguments.

Too few operands to instruction
The instruction statement requires more operands than were supplied. For example,

```
add ax ;missing second arg
```

Too many arguments to procedure
You called a procedure using too many arguments. For example,

```
foo proctype pascal :word, :dword
fooproc proc foo a1:word, a2:dword

endp
```
call fooproc,ax,bx,cx,dx ;Too many arguments.

Too many errors found
Turbo Assembler has stopped assembling your file because it contained so many errors. You may have made a few errors that have snowballed. For example, failing to define a symbol that you use on many lines is really a single error (failing to define the symbol), but you will get an error message for each line that referred to the symbol.

Turbo Assembler will stop assembling your file if it encounters a total of 100 errors or warnings.

Too many errors or warnings
No more error messages will be displayed. The maximum number of errors that will be displayed is 100; this number has been exceeded. Turbo Assembler continues to assemble and prints warnings rather than error messages.

Too many initial values
You have supplied too many values in a structure or union initialization. For example,

```
XYZ STRU
A1 DB ?
A2 DD, ?
XYZ ENDS
ANXYZ XYZ <1,2,3> ;error, only 2 members in XYZ
```

You can supply fewer initializers than there are members in a structure or union, but never more.

Too many register multipliers in expression
An 80386 scaled index operand had a scale factor on more than one register. For example,

```
mov EAX,[2*EBX+4*EDX] ;too many scales
```

Too many registers in expression
The expression has more than one index and one base register. For example,

```
mov ax,[BP+SI+DI] ;can't have SI and DI
```

Too many USES registers
You specified more than 8 USES registers for the current procedure.

Trailing null value assumed
A data statement like DB, DW, and so on, ends with a comma. TASM treats this as a null value. For example,

```
db 'hello',13,10, ;same as ...,13,10,
```

Undefined symbol
The statement contains a symbol that wasn't defined anywhere in the source file.
**Unexpected end of file (no END directive)**  
The source file does not have an END directive as its last statement. All source files must have an END statement.

**Unknown character**  
The current source line contains a character that is not part of the set of characters that make up Turbo Assembler symbol names or expressions. For example,

```
add ax,!'l ;error, exclamation is illegal character
```

**Unmatched ENDP:**  
The ENDP directive has a name that does not match the PROC directive that opened the procedure block. For example,

```
ABC PRO
XYZ ENDP ;error, XYZ should be ABC
```

**Unmatched ENDS:**  
The ENDS directive has a name that does not match either the SEGMENT directive that opened a segment or the STRUC or UNION directive that started a structure or union definition. For example,

```
ABC STRU
XYZ ENDS ;error, XYZ should be AB
DATA SEGMENT
CODE ENDS ;error, code should be DATA
```

**User-generated error**  
An error has been forced by one of the directives, which then forces an error. For example,

```
.ERR ;shouldn't get here
```

**USES has no effect without language**  
This warning appears if you specify a USES statement when no language is in effect.

**Value out of range**  
The constant is a valid number, but it is too large to be used where it appears. For example,

```
DB 400
```

**Variable length parameter must be last parameter**  
If a variable-length parameter is present, it must be the last parameter. For example,

```
foo proctype pascal :word, :unknown, :word ;Not allowed.
```
